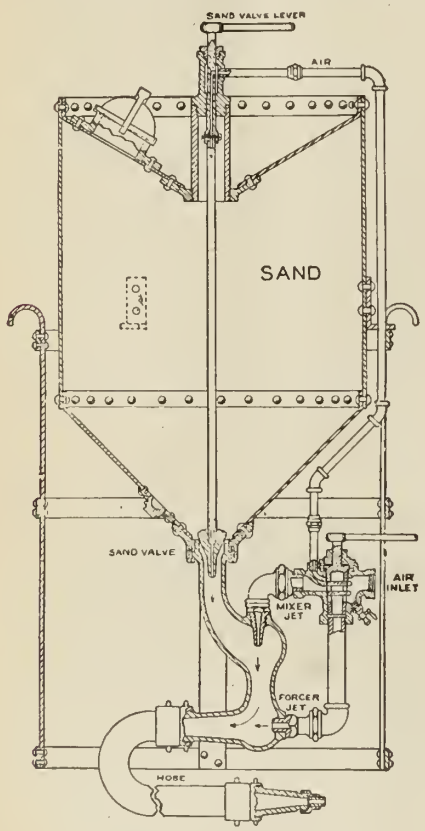
tage of a full circle swing, as does also the horizontal position, and any intermediate position.

Pattern makers' vises of the Emmert type have seven and six pairs of jaws, while the metal worker's vise has five pairs.

This vise is used very extensively throughout Great Britain and the United States, but this is its first introduction in Canada.

THE INJECTOR SAND BLAST.

Accompanying is an illustration of the injector sand blast apparatus as made by C. Druchlieb, New York, and in Canada by Canadian Rand Co., Montreal. This injector sand blast apparatus is an application of the injector principle, as commonly applied to steam injectors,



Injector Sand Blast Apparatus.

to the sand blast, the highest possible velocity necessary being imparted to the mixture of compressed air and sand by the several air jets, by means of which the quantity of the air can be controlled and directed, an essential feature to be found only in this apparatus.

With it castings can be cleaned, scale and rust removed from steel structural work, dirt and weather stains from the stone and brick work of buildings, and other and similar work performed, with the minimum amount of air, sand and pressure.

The injector sand blast apparatus comprises a steel or other sand tank suitably supported and provided with lugs for convenience in slinging. The top is depressed, allowing the tank to be easily filled, and the sand filling hole is closed by a special locking device. On the top of the sand tank is a small bonnet through which is led a vertical hollow stem terminating in the sand valve at the bottom of the tank. To balance the pressure on the sand, the air pressure is admitted to the sand tank through the vertical pipe shown outside thereof connected to the bonnet, the vertical stem being perforated.

Extending vertically through the sand valve is an air jet, admitting the compressed air into the injector casting, and producing a vacuum, which causes the sand to flow with evenness and regularity.

Below this jet is the mixing chamber, provided with a second vertical air jet, connected to the direct air supply, acting upon the mixture of air and sand and putting it into action, its velocity being increased by contracting the walls of the casting.

Below the mixing chamber is a third and horizontal air jet from the main air supply, forming with the enclosing casting, a forcer which delivers the mixed air and sand, now in very active motion, sharply and with full vigor to the work in hand, through a line of rubber hose provided with a special nozzle.

At one side of the sand tank and convenient to the hand is a special cock admitting and regulating the air supply consecutively to the sand tank, the central pipe and the several nozzles in the sand valve, the mixing chamber and forcer, or to all simultaneously, the supply of air being received from an air tank or compressor. A drain cock is provided to remove any condensation from the air.

The hose is connected to the mixing chamber by a patented, specially designed heavy hose coupling.

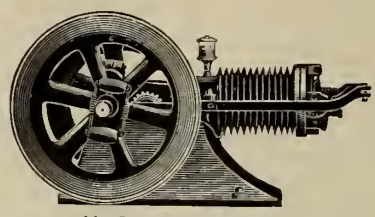
AN AIR-COOLED GASOLINE ENGINE.

The accompanying is an illustration of the air cooled small size gasoline engine manufactured by the Gilson Manufacturing Co., Ltd., Guelph, Ont. These engines are made in sizes from 1 to 5½ h.p.

The flanges around the cylinder provide a cooling surface of approximately 1,000 square inches in the 1½ h.p. engine and 1,400 square inches in the 2½ h.p. engine. Larger sizes are, in addition, provided with a fan with baffle plates which throws a current of air directly against the cylinder head. This fan can also be supplied to smaller engines, if desired.

The sparking plug, the intake valve and the exhaust valve, are all located in the cylinder head, and are, therefore, well cooled by the current of air.

Special attention is paid to the detail construction of this engine, compactness, neatness and accessibility of parts, be-



Air Cooled Gas Engine.

ing important features. The engines are so balanced that they can be operated without fastening the skibs, upon which the engine stands, to the floor.

STATIONARY ENGINEERS' CERTIFICATES.

The Legislature of Ontario at its recent session passed an act respecting stationary engineers in which engineers and employers are alike interested. Briefly stated, its provisions are that, after the 1st day of July, 1908, no engineer will be allowed to operate or have charge of a stationary steam plant of 50 horse power or upwards who does not hold a Government certificate. There are three classes of engineers to whom certificates will be granted without the applicant having to undergo an examination; first, those who on the 20th of April, 1907 (the date on which the act was passed), held certificates from an association of stationary engineers in Ontario, or a marine or locomotive engineers' certificate; second, engineers who on the above date were in charge of a plant of 25 horse power or over in Ontario; third, engineers who had at any time previous to the passing of this act, not less than two years' experience in the operation of such a plant in the province. Those who cannot qualify as above will have to pass the examinations which will hereafter be prescribed by the board of examiners.

Those interested may obtain a copy of the act and application forms for certificates by addressing the secretary, Department of Agriculture, Toronto.

Enough study has been spent on the subject to determine that men especially suited to any particular kind of labor, if supplied with proper implements and intelligently directed, can do on an average, at least three times as much as the average workman does, if the limiting factor is physical exertion and, if assured proper compensation, will do so day after day.

ABOUT CATALOGUES

By mentioning Canadian Machinery to show that you are in the trade, a copy of any of these catalogues will be sent by the firm whose address is given.

STEAM SPECIALTIES.—A little illustrated booklet issued by Darling Bros., Ltd., manufacturers of steam specialties, Mantreal. This booklet describes the different specialties made by this firm.

ELECTRIC PROPELLER FANS.—Bulletin 146 of the Sturtevant engineering series issued by the B. F. Sturtevant Co., Hyde Park, Mass., illustrating and describing their electric propeller fans.

J. T. SCHELL.—Three bulletins on the standard heading matcher, the standard heading turner, and the improved saw mill outfits, manufactured by J. T. Schell, Alexandria, Ont. These bulletins are illustrated and are of standard size.

GISHOLT LATHES.—An attractive catalogue of the Gisholt Machine Co., Madison, Wis., dealing with their turret lathes, boring mills, and tool grinders. This catalogue is well gotten up and well illustrated, and is 8 by 10 inches.

GARDNER'S GRINDERS.—A standard size, illustrated catalogue, descriptive of "Gardner's Improved" disc grinders, band polishing steel, disc wheel circles, and sectional wheel chucks, made by the Gardner Machine Co., Beloit, Wis.

STEAM BOILERS.—A catalogue issued by the Robb Engineering Co., Limited, Amherst, N.S., illustrating and describing the Robb-Mumford boiler. The catalogue is well illustrated and contains some interesting and useful data on steam boilers.

THE ROLLINS ENGINE.—Bulletin No. 15 of the Rollins Engine Co., 29 Mason St., Nashua, N.H. This bulletin gives detail description and illustration of the Rollins engine. Each important part is very clearly illustrated with half-tone engravings.

FOUNDRY FURNISHINGS.—A general catalogue of foundry supplies published by the Detroit Foundry Supply Co., Detroit, Mich. This catalogue is a handsome and most complete one; 431 pages, 9 x 6 in. It is well illustrated and contains a complete index.

THE BOWSER OIL TANKS.—Catalogue of S. F. Bowser & Co., Fort Wayne, Ind., illustrating and describing the Bowser self-measuring oil tanks and pumps for various purposes. The catalogue is well illustrated. The Toronto branch of this company is at 530 Front St. West.

THE MARION FEED-WATER HEATER AND PURIFIER.—Catalogue of the Marion Incline Filter & Heater Co., Marion, Ohio. This catalogue illustrates and describes in an effective way the operation of their feed-water heating and purifying apparatus, and points out its advantages.

BRICK MACHINES.—The McIntosh Brick Machine Co., of Goderich, is sending out some good literature to prove the merit of sand-cement pressed brick, and the machine which makes it. A pamphlet of convincing testimonials is enclosed with a neat and attractive catalogue.

BELL ENGINES AND THRESHERS.—A complete catalogue of the Robert Bell Engine & Thresher Co., Ltd., Seaforth, Ont., illustrating and describing their traction, portable and stationary engines, locomotive and stationary boilers, separators, saw mill machinery, belting, threshermen's and mill supplies; 88 pages, 5½ by 9½ inches.

ROBB-ARSTRONG ENGINES. — A complete and well illustrated catalogue of the Robb-Armstrong engines, giving a detailed description, with illustrations, of their manufacture. These engines include Corliss and slide valve engines, horizontal and vertical, simple and compound. A very complete description of parts is given.

PNEUMATIC APPLIANCES. — The general catalogue of pneumatic appliances manufactured by the Curtis Manufacturing Co., St. Louis. This catalogue includes a description of their air compressors, air hoists, bridge cranes, traveling cranes, trolley systems, jib cranes, and pneumatic elevators. The catalogue is well illustrated and is of standard size.

FIRE BRICK.—A very handsome catalogue published by Harbison-Walker Refractories Co., Pittsburg, Pa., containing useful information in connection with the use of silica, manganese, chrome and fire clay brick. The book is full of illustrations and contains a large number of tables, as well as space at the back for notes, memoranda, etc.

GENERAL ALTERNATING CURRENT DATA are given in Bulletin 74 just published by the Crocker-Wheeler Co., Ampere, N.J., entitled "Engine Type A. C. Generators." Views are shown of plants where Crocker Wheeler alternators have been installed, and details are given describing the design of generators developed by the company.

MACHINE MOULDING.—A most complete catalogue issued by MM. Ph. Bonvillain and E. Ronceray, 9 and 11 Rue des Envierges, Paris, with descriptive treatment of moulding sand, the universal system of pattern plate making, the universal hydraulic moulding plant, etc. This firm are exhibiting their machine at the Philadelphia convention of the American Foundrymen's Association.

ALMOND PRODUCT.—A very neat little catalogue issued by the T. R. Almond Mfg. Co., 83-85 Washington St., Brooklyn, N.Y., illustrating and describing the Almond product, including "Almond" drill chucks, right-angle transmission devices, turret heads, flexible arms for electric lights, electrical steel tubing. Illustrations are very suggestive, in that the important parts are brought out very prominently.

FROM NOVA SCOTIA.—Rhodes, Curry & Co., Amherst, N.S., have sent a very useful little souvenir, in the form of a card case and memo book. This is made of handsome maroon leather and lined with tan calfskin. The cover is free from advertising with the exception of the firm name and address, which appear in gold lettering. The above firm will be pleased, as long as the supply lasts, to send one to any in the trade who will mention Canadian Machinery when writing.

NOTES ON HIGH SPEED STEEL.—This is the title of an interesting little booklet on "Conqueror Tool Steel," issued by J. Beardshaw & Son, Baltic Steel Works, Sheffield, Eng.

This book contains much valuable information for users of tool steel, such as: Instructions for working "Conqueror" H. V. tool steel; forging; hardening of turning and planing tools; hardening of drills, milling cutters and tools of intricate shape; annealing; grinding, etc., besides interesting and instructive notes on ordinary tool steel.

Alexander Gibb, manufacturers' agent, 13 St. John St., Montreal, is sole Canadian agent for "Conqueror" tool steel, and he will be pleased to supply copies of this booklet to any in the trade who will mention Canadian Machinery when writing.

Industrial Progress

CANADIAN MACHINERY AND MANUFACTURING NEWS would be pleased to receive from any authoritative source industrial news of any sort, the formation or incorporation of companies, establishment or enlargement of mills, factories or foundries, railway or mining news, etc. All such correspondence will be treated as confidential when desired.

A large sawmill will be erected at New Westminster.

A new two-storey box factory will be erected in Toronto.

A large addition is being built to the Guelph Carpet Mills.

The Whitman-Barnes Co.'s works will remain in St. Catharines.

The London Fence Machine Co., London, will build this year.

The Toronto Engraving Co. will erect a new five-storey building.

Head & Co., bakers, will erect a $10,000 plant at Fort William.

Work on the new I.C.R. shops at Moncton is going on rapidly.

A $20,000 addition will be made to the Kuntz brewery in Waterloo.

The W. H. Malkin Co., Vancouver, will erect a new warehouse.

D. Fraser & Sons, Fredericton, N.B., will rebuild the Aberdeen mill.

Large additions are to be made to the Fraser River Tannery Company.

A new brickyard has been opened up in Wetaskiwin, Alt., by A. Geuz.

A new technical college will be erected at Halifax, to cost $100,000.

Mills & Anticknap are arrnaging to build a large tannery in Welland.

Efforts are being made to get the Ottawa Car Co. to move to Toronto.

The Phillips Mfg. Co., Toronto, will erect a factory at a cost of $83,000.

W. E. Shantz and H. Quelsdorf will build a furniture factory in Berlin.

The West Kootenay Power Co. have taken over the Cascade Power Co.

The electric light plant, Indian Head, will be extended at a cost of $25,000.

The Alberta Pacific Elevator Co. are building a large elevator at Calgary.

The Nelson Iron Works have started their new foundry at Greenwood, B.C.

Tenders for waterworks in Quebec, Regina and Thorold are being called for.

The Dominion Smelter Co. have decided to erect a smelter at Parry Sound.

The Bell Telephone Co. will erect an entirely new plant in Chatham, Ont.

Lymburner & Matthews, brass founders, Montreal, have dissolved partnership.

Mitchell & Phelan, have been registered in Montreal as iron and brass moulders.

The Breadner Mfg. Co., Ottawa, will erect a three-storey factory this summer.

A new carriage factory and warehouse costing $30,000, will be built at Winnipeg.

Frankel Bros., Toronto, will erect a two-storey warehouse, at a cost of $85,000.

The Gorman, Eckert Co., London, are spending upwards of $60,000 on a new plant.

Dyment, Baker & Co., London, are preparing plans for an extension this year.

The Krug Furniture Co., Berlin, will make a $10,000 extension to their factory.

The Fowler Canning Co., Hamilton, is doubling its capacity at a cost of $75,000.

The Ault & Wibourg Co. will build an ink factory in Toronto, at a cost of $35,000.

It is proposed to build a geological museum building for Toronto University.

A new winter fair building for Brandon, costing $30,000, will be built this summer.

The works of the London Fence Co., Portage la Prairie, Man., have been burned.

The Canadian Pacific Railway Co. may erect a station and a hotel at Fort William.

A power plant will be installed in the village of Strectsville, Ont., at a cost of $20,000.

The Stratford Gas Co., Stratford, will erect a large addition to their present plant.

The G.T.R. have let contracts for an enormous addition to their present shop at Stratford.

The E. W. Gillett Co., Toronto, will make a $30,000 extension to their present plant.

The Frontenac Gas Co., Quebec, will install a new plant at a cost of about $1,000,000.

E. Leonard & Sons, London, Ont., will erect a new plant in that city in the near future.

The Napanee canning factory is erecting a large addition to its already extensive plant.

The E. W. Gillett Co., Toronto, will build a four-storey brick warehouse, to cost $12,000.

The General Brass Co., Toronto, will build a one-storey brick factory at a cost of $9,000.

The Standard Fitting and Valve Company will build a $100,000 factory in Guelph this year.

The Sanitary Packing Co., Weston, Ont., will erect a new plant at a cost of about $20,000.

The Christie, Brown Co., Toronto, will erect a six-storey brick factory, costing $37,500.

Heintzman & Company, Toronto Junction, are building a large addition to their factory.

Wm. Berry, Brantford, will erect a factory for the manufacture of towels in Tilsonburg, Ont.

Extensive additions are to be made to the Vulean Boiler Works at New Westminster, B.C.

The Gananoque Belt Company, Gananoque, is spending $20,000 in additions and new machinery.

New Grand Trunk freight offices and additions to the freight sheds will be built at Brantford.

The Sydney Foundry Co., Sydney, C. B., are going to erect several new steel structure buildings.

The Montreal Rolling Mills Co., Montreal, have increased their capital from $816,000 to $1,200,000.

Several requests have been made for the right to develop power at the Big Chute, Severen River.

G. B. Reid, Toronto, will erect a two-storey brick factory on Sherbourne St., at a cost of $12,000.

The Grundy, Clapperton Co., Ltd., are to erect a factory for the manufacture of cut glass in Toronto.

Calgary ratepayers have authorized a loan of $250,000 to establish a municipal electric street railway.

The Virden Manufacturing Company, Virden, Man., will erect workshops in that place this season.

The Laprairie Brick Company, Laprairie, Que., are building extensive additions to their plant.

An addition to the roundhouse of the Canadian Pacific Railway Co. at Lethbridge, will cost $18,000.

The Malone-Manning wood fibre factory, which was burned out at Owen Sound, will be rebuilt.

The Gurney Foundry Company will expend $4,000 on an addition to their Toronto Junction plant.

The Imperial Varnish Co., Toronto, suffered heavily by fire caused by the explosion of a paint mill.

The Revelstoke Sawmills Co., Revelstoke, B.C., are to erect a sash and door factory at Moosejaw.

The Collingwood Shipbuilding Co., Collingwood, will double the capacity of their extensive plant there.

An electrical smelter for the treatment of iron ores will be erected on the shores of Burrard Inlet, B.C.

The Gundy, Clapperton Company, Toronto, will erect a cut glass manufacturing plant in that city.

Damage to the extent of $6,000 was done by fire to the Longue Pointe Cement works, near Montreal.

Steps are being taken by the Government to utilize the peat bags in Ontario and Quebec for fuel purposes.

The Canada Pride Wrought Iron Range Co., Toronto, will erect a $5,500 frame and metal factory in that city.

The Lantz Marble Company of Buffalo, are to erect a factory to cost $40,000 in the east end of Toronto.

A Bradshaw & Co., Toronto, will erect a factory at Toronto Junction for the manufacture of garments.

The Canadian Iron and Foundry Co., St. Thomas, Ont., are building a two-story brick pattern storage house.

The Canadian Pacific Railway have

let the contract for the construction of a large machine shop at Brandon.

C. K. Milne, Hamilton, has patented a new art or process of treating and preserving iron patterns from rust.

The Gananoque Spring and Axle Co. have been authorized to increase their capital stock from $150,000 to $300,000.

The Intercolonial Railway Co. are installing three 100 h.p. Robb-Mumford boilers in their shops at Moncton, N.B.

The growth of the business of the Copp Foundry, Fort William, for the first three months of this year was 69 per cent.

The Frontenac Gas Company, of Quebec city, will install a new plant this summer at a cost of one million dollars.

The Granby Co.'s smelter in British Columbia has been shut down for some time, due to the scarcity of coal and coke.

The Guelph Axle Works will extend its factory during the present year, the plans calling for a building 40 by 76 feet.

The town of Chatham are considering the installing of a gas engine plant in the civic lighting and water works station.

The Jobin, Marrin Co., Winnipeg, have found it necessary to double the capacity of their present large warehouse.

The Queen City Oil Company, Toronto, have filed plans for a $15,000 extension to their oil works and warehouses.

The Construction and Paving Co., Toronto, will build a two-storey iron asphalt paving factory at a cost of $12,000.

The veneer factory of Mulhall & Co., of Sundridge, Ont., was totally destroyed by fire on April 10th. The loss is $16,000.

The Bell Telephone Co. will build a branch exchange in Winnipeg, to cost $40,000, and a stores building, to cost $36,000.

H. Disston & Son, Toronto, have been granted a permit to erect a saw factory on Adelaide Street, to cost $10,000.

A meat packing plant will be built in Edmonton this year, at a cost of $500,000, and a brewery plant at a cost of $250,000.

The Battle Creek Health Food Co., London, have machinery on the way that will double the capacity of their new plant.

The saw mill owned by B. Grier, and the building occupied by the Bonner Leather Co., Montreal, have been destroyed by fire.

A large power house will be built in connection with the Canadian Pacific Railway hotel at Victoria, B.C., at a cost of $40,000.

The city engineer, Windsor, is advertising for tenders for the construction of 115,000 feet of cement walks to be laid this season.

The Gurney Foundry Co. will spend $4,000 in increasing the capacity of the moulding department in its works at Toronto Junction.

The London Street Railway Co., London, will erect an addition to their building and improve their equipment at a cost of $50,000.

The Amherst Foundry Co., Amherst, N.S., suffered loss by fire to the extent of $75,000. The enamelling department was completely destroyed.

A sub-committee of the board of works, Hamilton, have been appointed to look into the cost of establishing a municipal lighting plant.

W. H. Acton and T. W. Suddaby, of Gananoque, will establish a harness factory at Kingston, to be known as the Kingston Harness Works.

The new plant at North Battleford, Sask., will soon be in operation. Sand, lime, brick and artificial Indiana sandstone will be manufactured.

Messrs. Clarke & Clarke, Toronto, will erect their new factory at the head of Manning avenue. They sold their old site to the Canadian Northern.

The West Park Brick Company will Strathcona, Alta., have commenced the manufacture of ordinary brick, and later will establish a pressed brick plant.

Harry Cates, proprietor of the Brandon, Man., Pump and Windmill Works, has decided to build a large new brick factory and warehouse in that city.

The new machinery for the American-Canadian Oil Co., to be used in the development of the company's property at Morinville, B.C., is being installed.

The Brockville Light and Power Co., Brockville, Ont., are installing a new 72 inches by 18 feet return tubular boiler, made by the Robb Engineering Co.

The International Portland Cement Co., of Hull, Que., has increased its capital from $1,000,000 to $1,250,000, and its capacity to 3,000 barrels per day.

The Stanley Smelting Works will erect a new smelter at Kingston, where they will be granted a free site of five acres and ten years' exemption from taxation.

The American Institute of Mining Engineers will hold its annual convention in Toronto, opening July 23. The members will visit Temiskaming, Cobalt and Sudbury.

A syndicate at Virden, Man., will erect a large building for the manufacture of the Whiteford weighing machine, patents for which have been secured only recently.

Work on the plant of the National Rolling Mills, Sydney, N.S., will begin at once. This company has been organized by C. V. Wetmore and F. A. Crowell.

The Dow Cereal & Milling Co., Pilot Mound, Man., intend building a large oatmeal and cereal mill at Edmonton this summer, and are at present figuring on the cost.

The Thames River, Ont. at Big Bend, has been examined by H. G. Acres, assistant engineer of the Hydro-electric Power Commission, with a view to power development.

T. R. Booth, Ottawa, has started work on a new sulphide and paper board mill at the Chaudiere. The construction will be of concrete and the total cost $75,000.

Work on the plant of the National Rolling Mills, Limited, at Sydney, N.S., will begin at once. This company has been organized by C. V. Wetmore and F. A. Crowell.

The Perfection Power Pressed Cement Machine Co. have erected a plant in the Spring Ridge Sand Pits, B.C. They manufacture power pressed cement building blocks.

The ratepayers of Tillsonburg almost unanimously carried a by-law to loan William Berry, of Brantford, $15,000 with which to erect a large towelling and textile factory.

At the big industrial exhibition to be held in Winnipeg from the 13th to the 20th of July, 16,800 square feet will be set aside for a special display of "Made in Winnipeg" articles.

The third unit of the Electrical Development Company's power station at Niagara Falls has been installed and tested. It develops 13,000 h.p. A fourth unit is being completed.

Fire in the premises of J. A. Dawson, dealer in electrical and street railway supplies, 745 Craig St., Montreal, caused damage to the extent of over $15,000 on the evening of April 26.

The Anchor Wire Fence Co., of Stratford, are planning to build a new factory this summer. The proposed building is two storeys high and 100 by 50 feet. It will be built of concrete.

The long hoped for industrial awakening of Halifax seems to be approaching. The I.C.R. are erecting an extensive roundhouse, and the Silliker Car Works, are installing an up-to-date plant.

The City of London has asked the Ontario Railway and Municipal Board to approve of a by-law authorizing the issue of debentures to the amount of $25,250 for the extension of its waterworks system.

The Anchor Wire Fence Company, Stratford, are planning to build a new factory this summer. The proposed building will be two storeys high and 100 by 50 feet. It will be built of concrete.

The Alberta Portland Cement Co., Calgary, are installing a 500 k.w. direct connected generator to a Robb-Armstrong cross compound Corliss engine, 150 r.p.m., for lighting and power purposes.

The Robb Engineering Co., Amherst, N.S., have recently supplied the town of Truro, N.S., with a 150 h.p. Robb-Mumford water tube boiler, a duplex feed pump and a Robb feed water heater.

The Pacific Coast Mills & Timber Co. are planning to erect a large mill on this side of the international boundary. The site has not been chosen. Mr. B. H. Silver is opening up an office in Vancouver.

The old Frost & Wood factory in Oshawa, latterly occupied by John Stacey as a planing mill and sash and door factory, was destroyed by fire on April 26. The loss amounted to $20,000,

with insurance of $7,000. The factory will be rebuilt.

On account of finds of rich clay in Morris, Man., a company has been formed to operate a modern brickyard. Building operations will commence immediately under supervision of Mr. Windsor.

The International Heating and Lighting Co., Cleveland, Ohio, have secured an option on a site at Portage la Prairie and will begin the erection of a gas plant as soon as the deal can be put through.

Phillips and Buttorff Manufacturing Co., of Nashville, Ten., have recently added to their foundry equipment a 16 ton per hour Newton cupola, manufactured by the Northern Engineering Works, Detroit.

A company for the manufacture of freight cars is being organized at St. Thomas, Ont., with a capital of $400,000. It is said that the company can obtain a contract which will keep it busy for ten years.

Plans for a two-storey brick factory 50 x 150 feet, have been approved by the Canadian Brass Manufacturing Company, Galt. It is expected that building operations will be proceeded with at an early date.

The Dominion Iron & Steel Co., Sydney, are erecting 350 coke ovens. These, with the 500 now in use, makes 850. A new record was made on May 23. The three smelters on double shifts turned out 900 tons of metal.

The Alberta Government have set aside $200,000 for the construction of telephone lines into the province. Already a large number of long distance lines are under construction and several others are being planned.

The Page-Hersey Iron, Lead and Tube Co., Guelph, will immediately extend their present plant by the erection of a large new building, which, when completed and equipped, will double that firm's already large output.

Nova Scotia Steel & Coal Co., have purchased a large deposit of iron ore in Brazil. This is the first of Canadian industries to acquire foreign ore deposits. This ore deposit in Brazil is said to be one of the richest known of.

It is quite probable that an extensive car plant will be erected in Moncton, N.B. The Board of Trade are quite enthusiastic about it, recommending the city council to grant free water, light and a tax exemption for twenty years.

Scottstown, Ont., is bidding for industries. The municipal council has, by resolution, authorized a bonus of $10,000 as an inducement to any manufacturing industry that will invest $15,000 in a plant and pay out at least $12,500 annually in wages.

North Battleford, Sask., is to have a $75,000 sand lime brick works. Work on the factory will commence immediately and in two months the plant will be turning out 20,000 bricks a day. The Schwartz Brick Co., of New York City, are the promoters.

The Longue Pointe Cement Works, Longue Pointe, Que., suffered severely from fire. The whole interior of the factory was gutted. The works were of recent construction and equipped with modern machinery. A large addition was in process of construction.

A pressed steel car wheel plant is about to be established at Montreal, according to recent report. There are distinct advantages in this class of wheels over the usual cast wheels. Graham Fraser is the capitalist who is said to be behind the enterprise.

The Restigouche Woodworking Company's factory, of Dalhousie, N.B., was completely destroyed by fire last month. The boilers and engines were saved, but a large amount of manufactured lumber was consumed. The loss is estimated at $80,000, with insurance of $40,000.

A Canadian shipbuilding plant will be established at Fort William. The company which has it in charge is made up of prominent Chicago and Canadian capitalists. It is understood that an investment of $2,000,000 will be made for construction and working expenses.

The Diamond Coal Co. Calgary, are installing a 10-ton hand-power traveling crane supplied by the Smart-Turner Machine Co., Hamilton. The Standard Soap Co., Calgary, are putting in a single effect evaporator, built by the Smart-Turner Machine Co., Hamilton, Ont.

Mills & Anticknap, hide dealers and tanners, Welland, have been making experiments during the past few months, and have succeeded in perfecting a new method for tanning sole leather. They will build a large tanning establishment in that town, to carry out their new ideas.

The Canadian Pacific Sulphite Co., Swanson Bay, B.C., will shortly invite tenders for five large boilers and a large amount of heavy machinery for papermaking. The boilers will be of the horizontal tubular type, each seventy-two inches in diameter by twenty-two feet in length.

The Sydney & Glace Bay Railway Co., Sydney, C.B., are installing a new engine and boiler plant consisting of a compound Robb-Armstrong vertical engine, direct connected to 250 k.w. generator, a 250 h.p. return tubular boiler and a 500 h.p. Robb feed water heater and steam separator.

The new plant of the Michigan Copper and Brass Rolling Mills of Detroit will have two 5-ton, 3-motor electric traveling northern cranes. These cranes are of the low type, direct current design and have already been installed by the manufacturers, Northern Engineering Works, Detroit, Mich.

The town of Campbellford are voting on a by-law to authorize the issue of debentures to the amount of $15,000 for granting a bonus by way of a loan to Dickson Bros. to aid them in the erection of suitable buildings for the manufacture of steel bridges and other structural work within the said town.

One of the features of the exhibition at Atlantic City during the convention of Master Car Builders & Master Mechanics from June 12th to the 19th, will be the demonstration of the results to be achieved from the use of the file sharpener of the American File Sharpener Co., 296 Broadway, New York.

Dr. R. R. Stoner, Minneapolis, president of the Stoner Land Co., states that the company will establish a big brick plant near Medicine Hat. The capacity to start with will be 50,000 bricks a day, rapidly increasing to 100,000, and the class of brick manufactured will be pressed or repressed, and probably paving brick.

Owing to the difficulty of getting prompt shipments of mining machinery in the Cobalt district, there is a movement on foot to establish manufacturing plants in that district for the production of such machinery. It is estimated that $200,000 worth of mining machinery was shipped into the Cobalt during the past year.

Great extensions are being made to the Canadian Locomotive Works, Kingston, which will call for an expenditure of $300,000. The new power house will be equipped with the most modern equipment, and will cost $100,000. Some 600 men are working night and day now, and before two years 1,000 men will be busy in the works.

A plant for the extraction of by-products from wood will be established in Victoria, B.C. R. N. Calkins, a mechanical engineer, has been carrying on investigations for some time, and he has met with sufficient encouragement to cause him to organize a company for the extraction of tar, wood spirits, turpentine, and other products from fir wood.

The Huber Manufacturing Company, Marion, Ohio, is planning the establishment of a plant for the manufacture of agricultural implements at Portage la Prairie, Man., and to accomplish this have amalgamated with the Portage Iron and Machine Company. The new company expects to have one of the most complete machine establishments in the west.

Because they cannot get pig iron fast enough to supply the plant without buying in the American market at exorbitant prices, the Algoma Steel Company will at once commence the erection of a $1,000,000 blast furnace. Superintendent Lewis says it will be the largest furnace in Canada, and its erection will be followed at once with a big coke plant to supply the steel works.

McKenzie, Mann & Co., Toronto, Ont., have recently purchased from the Robb Engineering Co., Amherst, N.S., some boiler and engine room equipment, consisting of a Robb-Armstrong engine, direct connected to a 200 k.w. generator, a 10-inch by 10-inch vertical engine, two 67 inches by 18 feet return tubular boilers, a 250 h.p. Robb feed water heater and two duplex feed pumps.

Among the new buildings to be erected at Fort William during 1907 are the Grand Trunk Pacific elevator, 7,000,000 bushels, cost, $2,000,000 ; shipyards and dry dock, $1,000,000 ; Imperial Steel & Iron Works, $500,000 ; Consolidated Elevator Co., $200,000 ; Canada Iron & Foundry Co., $200,000 ; Ogilvie Flour Mills Co., $175,000 ; Canadian Pacific Railway coal docks and sheds, $77,500 ; Muirshead & Block elevator, $20,000.

What will undoubtedly by the largest installation of steam superheaters in Canada up to date, is that just contracted for by the Dominion Iron and Steel Co., Sydney, viz., thirty "Foster"

superheaters to be placed under eighteen Babcock & Wilcox type, and twelve Cahall type boilers of 250 h.p. each, a total of 7,500 h.p. This order was placed in the hands of Messrs. Laurie & Lamb, of Montreal.

The contract for the new Central Power Station at Washington, D.C., which has just been let by the United States Government, will mean the establishment of the largest plant of its kind in the U.S. The contract calls for sixteen 600 h.p. high pressure Atlas water tube boilers, and four 2,000 k.w. Westinghouse-Parsons turbines. The consulting engineers of the work are J. G. White & Co., of New York.

By-laws granting exemption and land to the Stanley Lead Company, Toronto, and the Grey & Hedley Zinc Company, on smelters to be established at Kingston were carried by the ratepayers of the Limestone City on Monday. The two companies will use part of the city's water lots below Cataraqui bridge. Buildings to cost $140,000 will be erected, and work will start at once. Lead and zinc will be received from the mines in North Frontenac, within easy distance of Kingston.

Among the orders received by the Smart-Turner Machine Co., Hamilton, for their standard duplex pumps are: the Midland Towing and Wrecking Co., Midland; Revillon Bros., Nipigon, Ont.; the Polson Iron Works, Toronto; the Port Credit Brick Co., Port Credit; R. J. Morrow, Collingwood; the Huntsville Lumber Co., Huntsville; the Highlander Lumber Co.; the Mineral Range Iron Mining Co., Bessemer, Ont.; the John Inglis Co., Limited, Toronto; the Atchison Co., Hamilton, Ont.; the Standard Soap Co., Calgary.

Iron ore assaying 61 per cent. hematite, has been discovered in Boggy Creek Valley, near Roblin, Manitoba, the fortunate prospectors being M. J. Galvin, Toronto, and T. Wagner, Buffalo, nephew of Senator Wagner, the Michigan iron magnate. Credit for the discovery belongs to Mr. Wagner, who made it while assisting in the construction of the Canadian Northern Railway Company's trestle across Boggy Creek several years ago. Since that time he and his associates have been quietly prospecting, and are confident that exceptionally rich deposits have now been found.

Medicine Hat has been getting many new industries of late. The latest is a powder company known as "The J. C. Mitchell Smokeless Powoer Company, of Canada." The company starts out with a capital of $100,000 and will manufacture powder said to be far superior to anything in the market in the explosive line. The new powder, called "Mitchellite," was invented by J. C. Mitchell after twenty years of experimenting. As soon as machinery can be procured, a plant with a capacity of 20,000 pounds per day will be installed. In the meantime 1,500 pounds per day will be manufactured by hand.

Chain Factory for Canada.

Application has been made to the Canadian Government by the Standard Chain Co., for a Canadian charter. As soon as this is granted the company propose to erect a plant at Walkerville, Ont., for the manufacture of chain. In this plant all sizes and grades of coil chain, log chain and harness chain will be manufactured. This plant, it is thought, will be in operation early in the fall.

Alex. Gibb, one of Montreal's leading manufacturers' agents, and who has represented the Standard Chain Co. in Canada for some time, was the promoter of this enterprise, and deserves considerable credit, in thus promoting industrial expansion of Canada. He will be on the Canadian board of directors, and will probably manage the sales of the company.

Equipping Rolling Mills With Electric Motors.

The Tennessee Coal & Iron Co. has recently placed an order with the Crocker-Wheeler Co., Ampere, N.J., for the complete electric motor equipment for its new steel rail mill at Birmingham, Ala. This order comprises fifteen of the special rolling mill motors which the Crocker-Wheeler Co. build.

Addition to the Canadian Corundum Wheel Co.'s Plant.

The Canadian Corundum Wheel Co., Hamilton, Ont., have just started fires in another large new kiln. This will enable the company to give better deliveries than they have been able to do in the past. There is a very large demand for vitrified wheels at the present time.

Large Order From the United States.

The Robb Engineering Co., Amherst, N.S., have recently received a large order from Vanderbeek & Sons., Jersey City, for a power-house equipment, and also other machinery. This equipment includes 14-inch. by 14-inch. Robb-Armstrong engine, a 72-inch. by 16-foot return tubular boiler, a 50-foot stack, a duplex steam pump, a complete, a complete rotary mill, and a complete lath mill.

Rolling Mills at Sydney.

The site has finally been decided upon for the National Rolling Mills Co., at Sydney, N.S.; and from a commercial point of view, it is almost ideal. Construction will begin immediately. The buildings at first will not cover all the property, leaving plenty of room for expansion. At present materials for railway construction and car building will be manufactured, but other departments will be added as the demand increases.

Wants Reciprocity in Coal.

Chas. S. Hamlin, in an address before the Pittsburg Traffic Club, said:

"The people of Massachusetts earnestly desire, among other things, that coal be made reciprocally free of duty between Canada and the United States.

"Canada buys more than three tons of bituminous coal from us for every ton we buy from her. On every ton we import from Canada we have to pay duty to our Government, and similarly every ton of bituminous coal imported into Canada must pay duties to the Canadian Government. It is not an overestimate to state that last year more than $1,000,000 of duties were paid to the Canadian Government by Canadian railroads alone on bituminous coal imported from the United States."

McKenzie & Mann to Build a Blast Furnace.

McKenzie & Mann have made application to the City of Toronto for a site in the vicinity of Ashbridge's Bay, supposedly for the erection of a blast furnace. It is understood, however, that plans are on foot for a more extensive plant than a blast furnace, probably locomotive and repair works for their railway. Many Canadian shops are at work on the Canadian Northern Railway Co.'s large equipment orders, calling for a total outlay of more than five million dollars. With the exception of the dining and sleeping cars all of this business goes to the Canadian works.

The claims of the Dominion Iron & Steel Co. for bounties on their product during the months of January, February, March and April call for a total payment of almost $400,000.

Foundry and Machine Shop for Sydney.

The latest addition to Sydney's industries is the Sydney Foundry & Machine Works, Limited, which was recently incorporated, with Jas. Clarke, as president; W. E. Clarke, secretary-treasurer, and H. C. Burchell, J. A. Young, J. T. Burchell, A. A. McIntyre and Henry McDonald, directors. The new company has taken over the business carried on during the past nineteen years by Messrs. J. and W. E. Clarke, known as the Sydney Foundry & Machine Works. Arrangements have already been completed for the installation of modern forging machines and a complete plant for the manufacture of steel castings, bolts, rivets, spikes, etc. New buildings will also be erected. The capital stock of the company is $100,000.

Neat Envelope Opener.

Flockton, Tompkin & Co., Limited, Newhall Steel Works, Sheffield, makers of the "Cat" brand of steel for engineers, miners, etc., are sending out a very neat envelope opener; an article always useful to the man at the desk. It is of bright polished steel, somewhat in the form of an open pocket-knife, with the name of the makers and the "Cat" brand neatly brought out on the solid handle.

To Enlarge Brass Foundry.

W. R. Cuthbert & Co., Montreal, brass founders, have obtained a vacant lot adjoining their property and purpose, during the present year, to enlarge their premises and give employment to about five hundred additional men. The improvements will cost the firm $100,000.

Companies Incorporated

The Provincial Construction Co., Ltd., Montreal; capital, $20,000; purpose, to carry on the business of contracting; directors, J. P. Pauze, H. Baurgard, and others, all of Montreal.

Canada Office Furniture Co., Ltd., of Montreal; capital, $35,000; purpose, to manufacture and deal in furniture, etc.; directors, D. Wishart, D. E. Turner, F. A. Wishart, all of Montreal.

Northern Oil and Gas Co., Montreal; to carry on a general refinery business; capital, $90,000; incorporators, J. M. Fortier, M. Marchand, L. M. Fortier, J. A. Mann and S. W. Ridenour.

Shaw & Mason, Limited, Sydney, N. S., has been organized with a capital of $100,000 to manufacture brass and cast-iron fittings. The company will be the only one of its kind in Nova Scotia.

The Wm. Strachan Co., Ltd., Montreal; capital, $100,000; purpose, to manufacture soaps, perfumes, etc.; directors, G. W. MacDougall, L. MacFarlane and C. A. Pope, all of Montreal.

Frame and Hay Fence Co., Stratford; to manufacture and deal in wire fences, gates, and other fencing materials; capital, $100,000; incorporators: R. S. Frame, D. D. Hay, R. B. Murray.

Structural Steel Co., Ltd., Montreal; capital, $500,000; purpose, to carry on bridge building, and to manufacture structural iron; directors, T. Johnson, W. C. McIntyre and others, Montreal.

The Folding Box Co., Ltd., Owen Sound; capital, $49,000; purpose, to manufacture folding wooden boxes; directors, Matthew Kennedy, Norman Ross and A. G. McKay, all of Owen Sound.

The Mergenthaler Co., Ltd., Toronto; capital, $49,000; purpose, to manufacture and deal in linotype, type casting and composing machines; directors, J. D. Montgomery, R. A. Montgomery and

Crown Canister Co., Dundas; to manufacture and deal in canisters, dies, wire and paper goods and metal ware; capital, $40,000; incorporators: R. R. Gamey, S. Metcalfe, W. B. Bentley, Jas. Watt, Jr.

The S. Cote Motor Co., Ltd., Montreal; capital, $20,000; purpose, to manufacture and deal in gas and gasoline engines, steam engines, etc.; directors, Simeon Cote, A. Meunier and R. LucPieur, all of Montreal.

The Perrin Shocker Mfg. Co., New Liskeard, Ont.; capital, $100,000; purpose, to manufacture and sell agricultural implements.; directors, Thos. McCamus, Wm. J. Emmerson, and J. L. Brown, all of New Liskeard.

J. W. Harris Manufacturing Co., Ltd., Montreal; capital, $1,000,000; purpose, to carry on business as engineers, shipbuilders, founders and contractors; directors, Thos. Craig, W. B. Powell, H. C. Mussen and J. W. Harris, contractor, all of Montreal.

The Standard Sanitary Mfg. Co., of Canada, Ltd., Toronto; capital, $20,000; purpose, to manufacture cast iron and enamel ware, brass goods, soil pipe, and other plumbers' supplies; directors, G. S. Hodgson, H. W. Maw, C. T. Gillespie, all of Toronto.

The Twin City Oil Company, Berlin, Ontario; capital, $40,000; to manufacture and deal in all kinds of oils, greases and compounds. Provisional directors: V. O. Phillips, J. A. Phillips, R. Richmond, C. N. Huether and Elizabeth Ann Phillips.

The Dictograph Company of Canada, with head office in Toronto, has been formed, with a capital of $250,000. The company have been authorized to manufacture dictographs, electrical, acoustic, and office specialties, as well as labor saving devices of all descriptions.

The St. Simeon Lumber Co., Ltd., St. Hyacinthe, Que.; capital, $290,000; purpose, to carry on the lumber trade in all its branches, including the building and operating of saw mills, etc.; directors, Ovide Brouillard, Michael Archambault, J. P. P. Robert, J. A. Tellier, all of St. Hyacinthe.

Standard Fitting & Valve Co., Ltd., Guelph; capital, $100,000; purpose, to manufacture cast and malleable iron fittings, valves, etc., and to carry on business as foundrymen and machinists; directors, Henry Aird, G. W. Aird, E. S. Platt, Troy, U.S.A., and J. M. Taylor, G. D. Forbes, Guelph.

National Refining Company, Toronto; capital, $20,000; to carry on the business of buying, selling, smelting and refining ores and metals, and to deal in dental and other trade supplies. Provisional directors: W. M. McTavish, R. A. McTavish and R. J. Dunlop.

The Wilson Automobile Co., Ltd., Ottawa; capital, $145,000; purpose, to carry on the business of mechanical engineers and manufacturers of automobiles, motor boats, engines and other machinery; directors, B. S. Wilson, H. R. Wilson and G. H. Wilson, all of Montreal, and S. H. McKay, of Ottawa.

Sterling Gas Company, Port Colborne, Ontario; capital, $40,000; to obtain oil or gas by drilling for the same or by any other means and to pipe the same and to deal in and with oil or gas. Provisional directors: M. A. Reeb, C. E. Steel and Mary Elizabeth Reeb.

The Ontario Steel Tubular Axle Co., Belleville, has been incorporated with a capital of $20,000 to manufacture and deal in steel tubular axles, and to carry on a foundry machine shop. The provisional directors are: H. P. Thomas, R. E. Colling, J. S. McKeown, W. J. Thomson, J. W. Boyd and J. C. Panter.

Imperial Supply Co., Montreal; to manufacture railway, marine and contractors' supplies, either in metal or wood; capital, $100,000; incorporators: Herbert H. Bradfield, Harry H. Bradfield, W. R. Duckworth, H. G. Myers, C. A. Myers.

Harriston Stove Co., Harriston, Ont., to manufacture stoves, ranges, heaters, furnaces, tools, machinery, etc., etc., and to take over as a going concern the Canada Stove Works of the same town; incorporators: J. E. Cave, F. Blacker, F. Burger, Jas. F. Hinde, Anson Spotton.

CONDENSED ADS.

RATES

One insertion—25c. for 20 words; 1c. a word for each additional word.

Yearly rate—$2.50 for twenty words or less, 10c a word for each additional word.

The above does not apply to notices under the head of "Machinery Wanted." These notices are inserted free for subscribers.

BUSINESS CHANCES.

WANTED—First-class foundry and machine company to buy interest in high-class patented machine, weighing seven tons and to manufacture, sell and instal same; this is a good proposition and will stand investigation. Apply Box 26, CANADIAN MACHINERY, Toronto.

A GOOD cash paying electric wiring business; a small capital only required; selling out owing to ill health. For particulars apply to Box 31, CANADIAN MACHINERY, Toronto. [8]

MACHINERY FOR SALE.

BELTING, RUBBER, CANVAS AND LEATHER, Hose, Packing, Blacksmith's and Mill Supplies at lowest prices. N. Smith, 138 York Street, Toronto. (2tf)

MANUFACTURERS' AGENTS WANTED.

SHEFFIELD manufacturers of tool steel, spring steel, section bars, etc., as advertised on page 13, wish to correspond with reliable Canadian firms with view to sole agencies in certain territories. Address "Newhall," care CANADIAN MACHINERY NEWS, 88 Fleet Street, London, Eng.

SITUATION VACANT.

WANTED—Young man well experienced in machinery supply business able to sell and knowing thoroughly all requirements of the trade. Salary, commission and share of profits. Apply Box 32, CANADIAN MACHINERY, Toronto.

SITUATIONS WANTED.

ADVERTISER, shortly emigrating, seeks position as correspondence clerk and accountant. Well up in all details of engineering and allied business; ledger, balancing, shorthand and typewriting excellent. References Lister, Ipswich Road, Ardleigh, Colchester, Eng.

ASSISTANT GENERAL MANAGER, McGill graduate, desires change of position. Twelve years' practical experience along engineering, machine, foundry and boiler shop lines. Best of references. Address Box 25, CANADIAN MACHINERY, Toronto. [3]

Motors and Launches

I have the following new complete launches about ready for delivery:

Power Skiff, 20' by 4', fine finish, equipped with 2 h.p. Erd Motor, $190.00.

Launch, 22', 4'6" beam, cedar planking, turtle back deck, torpedo stern, equipped with 7½ h.p. 2 cylinder Erd motor, speed 10 miles an hour, $375.00.

Launch, 25' by 6' beam, cedar planking, quartered oak deck and coaming, equipped with 10 h.p. 2 cylinder Erd motor, speed 11 miles per hour, $550 00.

Erd motors from 2 h.p. to 30 h.p., from $65.00 to $600.00, also one 10 h.p. Buffalo 4 cylinder 4 cycle marine motor, as good as new, $250 00.

One 3½ h.p. Trebert, complete with reversing wheel, used only one season, $400.00.

One 6 h.p. Gillies stationary gasoline engine, cheap.

One 18' by 4'9" clinker built launch, equipped with 2½ h.p. Norwalk engine, launched Sept. 1906, speed 8 miles per hour, a bargain at $225.00.

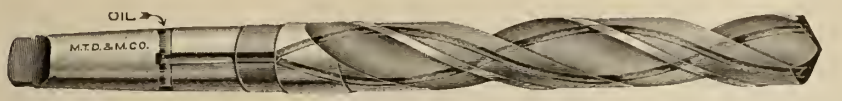
DRILLS WITH LUBRICATING HOLES



If you want to make a hole at a maximum of speed, and at the same time with the greatest accuracy, use one of our drills with holes from shank to point for conveying oil or other lubricant to the point of the drill. The general advantages of this form of lubricated drill over the ordinary twist drill are the greatly increased speed possible in drilling, the assistance given by the lubricant in the discharge of the chips, its durability and high cutting efficiency. The sizes commonly used are from ⅜ inch to 2½ inches diameter. Our drills have the lubricating hole through the solid metal, this latest improvement in lubricating drills being made solely by us under patents which we own. The special advantage of this drill over the other makes of drills with lubricating holes is that it is composed of one solid piece of steel; there is no part to work loose or wear out, the whole of the drill having the same life. In manufacturing large quantities of a single article having a drilled hole, one of our drills is invaluable. This is because of its long life, the speed at which it can be run without getting too hot for use, and the time saved by not having to withdraw the drill from the hole to cool it or to remove the chips.

OPAL GLASS TILING

FOR WALLS OF

MACHINERY AND POWER HOUSES

Most approved material.

TORONTO PLATE GLASS IMPORTING CO'Y

PLATE AND WINDOW GLASS

135 to 143 Victoria St., - Toronto

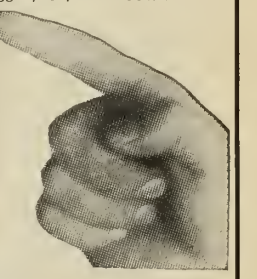
Globe Tumblers

admit of a perfect adjustment in the degree of action on the barrels' contents—regulated by the hand wheel at the side. Sheet metal stampings and small castings can be operated upon WITHOUT injury. You can see what you're doing and can remove the tumbled parts in one operation without cumping all over the floor. One legged, too, saves room and dirt.

Send for "THE SILENT PARTNER."

The little magazine that's the talk of the trade. Bright—brainy—good reading. Sample copy free. Also, we send our new tumbler hook.

WRITE US.



The Globe Machine & Stamping Co.

899 Hamilton St.

CLEVELAND, - OHIO

PIPE CUTTING AND THREADING MACHINES

FORBES Patent Die Stock

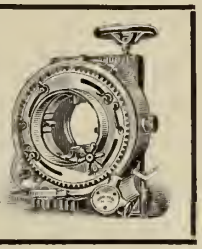
For Bench or Trench, Hand or Power. Range from ¼ to 15 inches.

PORTABLE, SIMPLE, STRONG, DURABLE.

WRITE FOR CATALOG.

THE CURTIS & CURTIS COMPANY,

36 Garden Street, Bridgeport, Connecticut



No. 56 Hand Machine, Range 2½ in.—6 in. R.H.

A NEW TRANSFER CAR

For Street Car purposes, operated by only one man, with a single lever. No motors required. New design.

ST. CLAIR BROS., - - - - GALT, ONT.

Are you a manufacturer of

Power Equipment, Machine Shop Equipment, Foundry Equipment and Supplies or Metal-working Tools of any class?

If so, you should be represented in these columns. An advertisement here will place your claims for their business before practically every buyer of these lines in Canada.

A post card will bring rates and further particulars

BUILDERS' SUPPLIES — TORONTO

TOOL ROOM ECONOMY :—

The Use of Diamo-Carbo Emery Wheel Dressers.

The ***Diamo-Carbo Dresser*** is the only satisfactory substitute for the black diamomd. Permits you to true and shape your wheels just the same as with the more expensive device, and is adapted for use on all tool grinding wheels. The hardest abrasive known; wears indefinitely; and cannot get lost or broken and will not injure the edges of the most delicate wheels.

Made in three lengths: 8", 10" and 12" respectively.

Prices: $3.00, $3.50 and $4.00

Tell us which length is best suited for your needs, and let us send a Dresser on ten days' trial. Booklet and testimonials for the asking.

Graphite Paints

IT is well known that Graphite makes one of the best paints as a preservative of exposed metal work. It is the best paint to use for iron castings or girders on account of its filling properties thereby giving it a good covering.

Machine Paints

BESIDES the ordinary, our machine paints are made in paste form and can be used as a filler, applied with a knife or thinned with turpentine and brushed on, spreads freely and leaves a good surface.

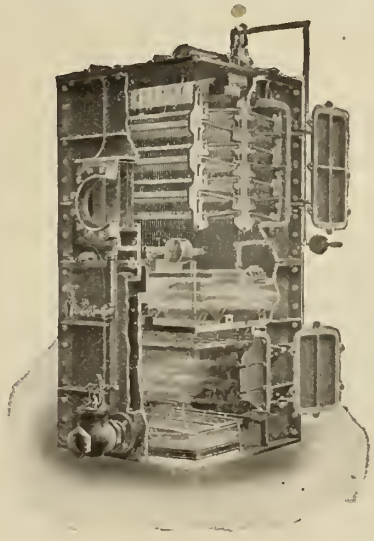
A Money Saver



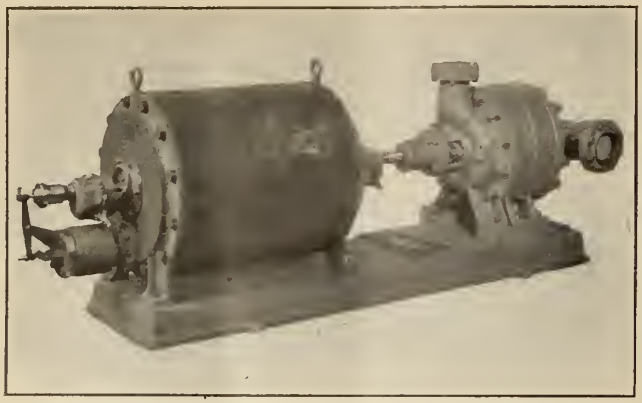
Money saved is money made. A wasteful heating system makes serious inroads into the net profits. We do not say that you should instal a Webster Heater, but we do say that you should know more about

THE WEBSTER
FEED-WATER HEATER
PURIFIER AND FILTER

and investigate the solidity of the claims we make for it before investing a dollar in any heating system manufactured anywhere at any price.

The type shown in the cut does save money. It cannot waste steam. It does not waste fuel. It is economic even although it affords the highest temperature. ***You*** should know more about it.

DARLING BROTHERS, LIMITED
Toronto Montreal Winnipeg



Kerr Turbine Pumps for water works, condenser equipment and boiler feeding. These pumps are more economical than direct acting piston pumps, and require less attention, lubrication and space. No belts or gears. Speed adjustable to pressure desired. Regulation close. Start and stop quickly. For any capacity.

Turbine Blowers for gas works, foundries and forge shops Air pressure 4 to 16 ounces. For any capacity.

Turbine Generators, 2 kw. to 300 kw. direct current and alternating current, 25 to 300 kw., 60 cycle.

The illustration shows an 18-inch condensing Kerr Steam Turbine coupled to a 4-inch 3-stage Worthington Pump. Capacity 200 g.p.m. against a head of 360 feet.

How Canadian Manufacturers Can Increase Their Export Trade

THE world's markets are worth securing—and the foreign trade situation is particularly favorable to Canadian manufacturers. How well the **American Exporter** is serving Canadian manufacturers in the export field is shown by the fact that nearly a score of large Canadian firms are now represented abroad by this publication. One Canadian firm that has carried an announcement continuously in the **American Exporter** for almost **thirty years**—from its first issue—makes an interesting statement regarding the results thus obtained that other Canadian manufacturers will find it profitable to carefully consider.

If you want to share in the tremendous foreign trade that is now flowing toward the manufacturers of Canada and the United States, write to-day for our specific information on the subject.

Advertisers for 30 Years

The American Exporter continues to be a successful advertising medium for those looking for an extension of foreign trade. As we wrote you some time ago, as advertisers in the publication from the beginning, we have been interested in its development, which seems to have been a steady and continuous one, due largely, we think, to the correct principles upon which it has been conducted. We have had good results from our advertisements in it, and believe that **there is no better advertising medium for securing foreign trade.**

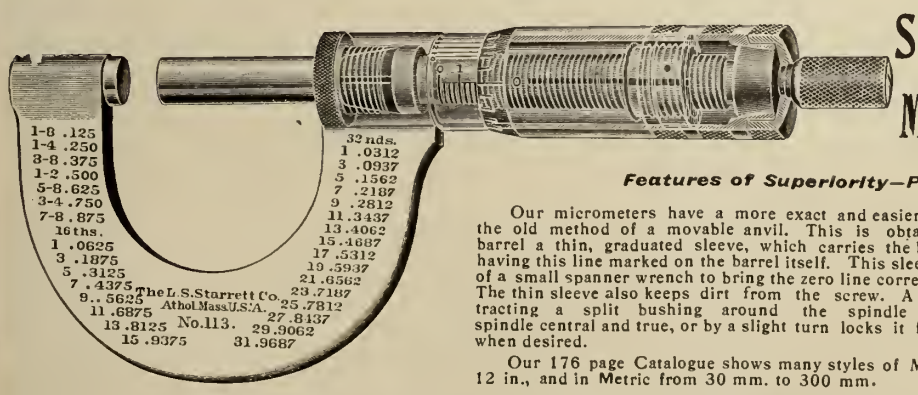
STARRETT TOOLS

ARE THE STANDARD

FOR ACCURACY, WORKMANSHIP, DESIGN AND FINISH



Starrett Micrometers

Features of Superiority—Patented

Our micrometers have a more exact and easier way of adjustment than by the old method of a movable anvil. This is obtained by placing over the barrel a thin, graduated sleeve, which carries the base or zero line, instead of having this line marked on the barrel itself. This sleeve may be turned by means of a small spanner wrench to bring the zero line correct to compensate for wear. The thin sleeve also keeps dirt from the screw. A knurled locking nut contracting a split bushing around the spindle tightens and keeps the spindle central and true, or by a slight turn locks it firm, making a solid gauge when desired.

Our 176 page Catalogue shows many styles of Micrometers, from ½ in. to 12 in., and in Metric from 30 mm. to 300 mm.

"ENGINEERING," besides a great variety of Illustrated Articles relating to Civil, Mechanical, Electrical and Military Engineering and Notes of General Professional Interest, devotes a considerable space in each issue to the illustration and description of all matters connected with the PRACTICAL APPLICATION OF PHYSICAL SCIENCE, and with its Wide and Influential Circulation in all parts of the world, this Journal is an

UNRIVALLED MEDIUM FOR ADVERTISEMENTS

SPECIAL NOTICE TO CANADIAN SUBSCRIBERS The Publisher of ENGINEERING desires to call attention to the important reduction in the subscriptions for Canada Owing to the new arrangements with the Dominion Post Office, the postage rate for newspapers is now Id. per pound, and the annual subscriptions for ENGINEERING posted direct to Canada will, until further notice, be

Thin Paper Copies	£1 11 6
Thick "	£1 16 0

Subscribers residing abroad are strongly recommended to order copies on thick paper, as the illustrations are necessarily very much less effective in the thin paper edition, and to remit, when possible, by Post Office Order made payable at Bedford Street, Strand, London, W.C. When Foreign Subscriptions are so forwarded, advice should be sent to the Publisher.

Foreign and Colonial Subscribers receiving Incomplete Copies through Newsagents are requested to communicate the fact to the Publisher, together with the Agent's Name and Address.

Cheques should be crossed "Union of London and Smiths Bank, Limited, Charing Cross Branch."

All accounts are payable to "ENGINEERING, LIMITED."

A GOOD INVESTMENT

If the ablest practical men in the machinery manufacturing industry were asked to name the best investment in their line the answer would be

The 22-inch ALL-GEARED LATHE

manufactured by **The London Machine Tool Company, Limited,** and we're ready to prove to you that they would be right.

Do you believe in carrying on business in the least expensive way ? Then this Lathe will satisfy you.

It is a money **saver** because of its **time** saving qualities. This Lathe has many features which make for Lathe perfection.

Head consists of six gears of wide face and coarse pitch, working into positive clutches, giving four changes of speed in geometrical progression. With three-speed countershaft, twelve speeds are obtained.

The spindles are manufactured from high carbon crucible steel and first bored from the solid stock roughed out on the lathe, final finishing cuts taken, then put on grinder and ground true to standard sizes.

But—Our literature gives full particulars of this **Money-Saving Machine** and we'd like your opinion, as a practical man, of our last achievement.

***IMPORTANT*—We can make quick delivery on above size.**

The London Machine Tool Company

HAMILTON, ONTARIO LIMITED

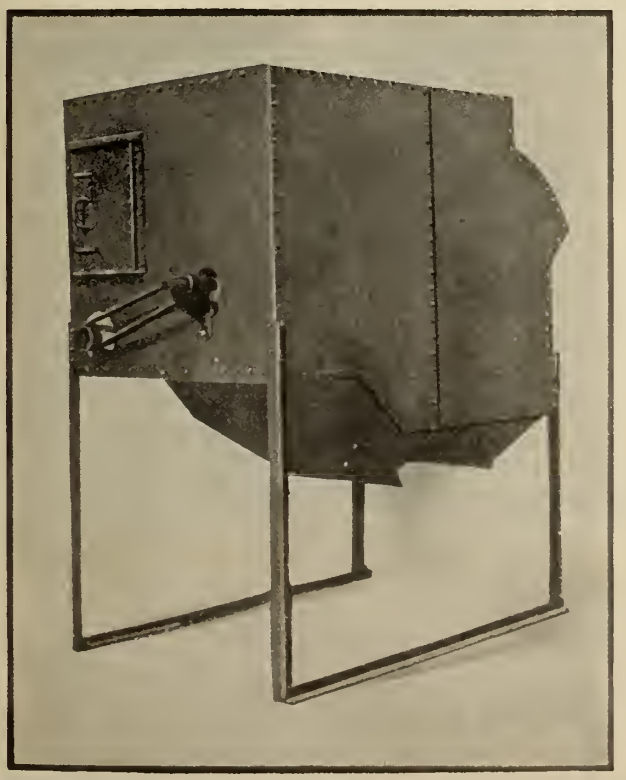
CORE SAND CLEANER



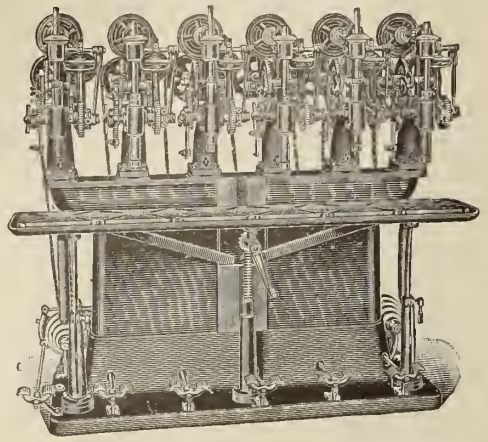
In many places core sand is expensive and hard to get. The cut shows our new core sand cleaner. This machine removes the fine dust and burnt bond from old core sand, and leaves the sand porous and ready for use again. By the use of this machine the sand may be used over and over continuously, by adding new sand to keep up the supply. Cores made of sand recovered by this machine are less liable to blow than those made of new sand, because the sand from old cores has been gassed off by the heat in former casts. It is self-contained and complete in itself, motor and fan inside out of the way and out of the dust. It is also portable. Four men can pick it up and carry it to any part of the foundry.

The W. W. Sly Mfg. Co.

CLEVELAND, OHIO

AUTOMATIC GANG DRILLS

BUILT FOR BUSINESS



These machines have independent self-operating spindles. Built in two, three, four and six spindle styles, 14-inch, 20-inch and 23-inch swing.

They are the latest machines in shop practice for most rapid and economical output.

Complete catalogue ready for those interested.

CARBORUNDUM
NIAGARA FALLS

LET our experts prescribe for your grinding needs.

Grinding is a scientific operation these days.

Manufacturers rightly demand, not merely a grinding wheel, but the most economical grinding wheel that can be produced.

And the Carborundum Company's trained experts are here to supply the demand.

There are something like 200,000 different sizes and grits and styles of wheel regularly made, and a lot more that are made to order for special purposes—

And each individual wheel does some one thing better than any other wheel.

If you will write us your grinding needs we will be glad to tell you the wheel best suited to your particular requirements.

Let us send you the Carborundum book.

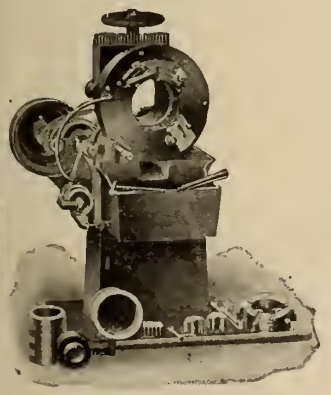
The LOEW MANUFACTURING CO., CLEVELAND, OHIO

The Big Result of Many Little Perfections.



This Combination Hand and Power, Portable or Stationary Merrell has been made the BIGGEST machine on the market by paying careful attention to the little things.

Big in its power to do MORE work--and BETTER work--under continuous strain than any other machine. Big in its power to work equally well when used as a hand or a power machine--and when used as a stationary or portable threader; and big in the fact that it is the only machine that will thread, satisfactorily, pipe up to 12 inches in size when in use as a portable hand machine.

And though big in achievements you'll not find the cost proportionately large.

We'll gladly send you this machine on 30 Days Free Trial.

Will you write to-day?

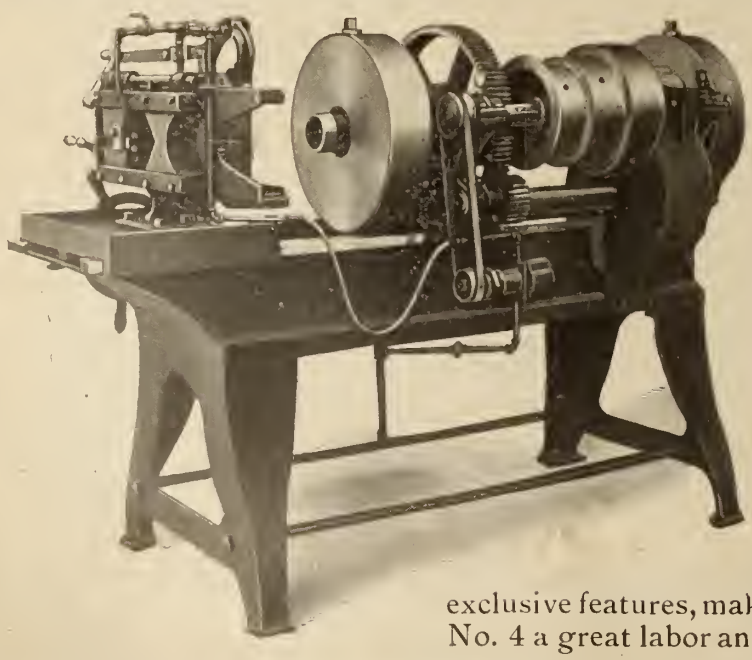
Shantz No. 4

Pipe Cutting and Threading Machine



THIS machine is fitted with the "Borden Patent Solid Adjustable Die Head" which is the easiest operated and most perfect mechanism invented. Any degree of accuracy may be obtained simply by the adjustment of an adjusting screw upon which the operating lever rests. Any variation may be obtained to suit any make of fitting, whether standard or not.

No backing off; just raise the lever and the pipe is released.

Change of dies easily and quickly made.

Universal chucks for gripping the pipe are placed on the front and rear ends of the arbor

In buying a Pipe Threading Machine the shrewd buyer demands **Rapidity, Accuracy, Strength** and **Simplicity.** These qualities, with the many exclusive features, make the Shantz No. 4 a great labor and time saver.

Convention of Waterworks Association

Large Number of Prominent Engineers Present—Many Interesting Papers Read and Discussed —Social Enjoyment in Trolley Ride and Moonlight Excursion—Display of Waterworks Supplies.

During the week of June 16 to June 22, there was gathered in Toronto a large number of prominent engineers from Canada and the United States at the twenty-seventh annual convention of the American Waterworks Association. In all there were five hundred active members, associate members and guests registered at the convention headquarters, in the King Edward hotel. Of these, two hundred were active members. This was a busy convention, evening, as well as morning and afternoon sessions, being held.

Group of Delegates Attending Convention of American Waterworks Association, Toronto, June 17-22.

The trolley ride around the city, on Wednesday, and the moonlight excursion on Thursday evening were practically the only digressions the members took from work.

The ladies were suitable entertained.

There was a goodly representation of manufacturers and supply men. The exhibits consisted chiefly of brass goods.

Conducting a Municipal Waterworks System.

The opening day, the second day, of the convention, was taken up in speeches of welcome, and in the discussion of the best methods of conducting a municipal waterworks system.

A strong argument in favor of the installation of meters on all water services was presented by Mr. W. Volhardt, of Staten Island, N.Y. He urged the necessity of meters, both on account of the desirability of curtailing waste and of giving a square deal between all classes of consumers, and advocated the installation of a universal system at the beginning.

Mr. George W. Rafter followed with a paper on "The Cost of Meters in Rochester, N.Y.," showing that the use of meters did not reduce the use of water. He made the deduction that water takers by meter paid 100 her cent. profit to the city at 14 cents per 1,000 gallons, while those taking water at fixture rates received it at far less than cost. These deductions were questioned by Superintendent Little, of the Rochester waterworks, and also by Mr. Fisher, Rochester.

James L. Tighe, of Holyoke, Mass., read a paper on "Water Consumption, Waste and Meter Rates." In Holyoke, the waterworks, although owned by the city, pay taxes just the same as a private corporation. The water consumption there increased from 85 gallons per capita in 1895, to 142 gallons in 1903, and 150 or 160 in 1904, A more vigilant inspection succeeded in reducing this to 114 gallons in 1906. This showed the ill-effect of allowing extravagances in the use of water.

Mr. Saunders, of London, raised the question of the economy of restricting the consumption of water when it cost more to do it than to pump all the people wanted. Mr. Volthardt, in reply, gave an experience in which after putting in meters, he had got back in fourteen months the entire cost of installing the meter system.

Dangers of Filter Plants.

J. M. Diven read a paper on "The Care of a Mechanical Filter Plant." He considered a filtered water supply as not an unmixed blessing, as much depended on how it was operated. There was a chance that the people would be worse off than before, as filter beds made excellent breeding grounds for bac-

teria, and water users were liable to forego all ordinary precautions and depend on the filtration plant alone. A properly trained man was required for a filter, one who understood its workings and had some knowledge of bacteriology.

Detecting Waterworks Losses.

At the evening session Mr. Edward S. Cole, of New York, gave a paper on the pitometer and waterworks losses, which was illustrated by lantern slides. The question of waste he considered the most important on account of the great expense entailed by it, but with the portable Pilot tube, he considered that there was now no excuse for permitting underground losses.

Producer Gas Plants.

The progress in economics in steam consumption was discussed by Capt. H. G. H. Tarr, of Buffalo. The only hope of relief from the heavy expense he hoped to find in the gas engine. This he illustrated by the record of a gas plant established at Poughkeepsie, N.Y., in 1905, which had given great satisfaction. The percentage of waste in the extraction of power from coal was estimated to be 90 per cent., and the saving with a gas plant was shown to be very great.

Mr. F. A. Barbour, of Boston, told of pumping water by a producer gas plant at St. Stephen, N.B.

Cost of Electrically Operated and Steam Pumps.

The morning session of the third day of the convention was taken up pretty fully in the discussion of electrically driven turbine pumps in comparison, as to cost, with steam pumps. The election of officers and the choosing of the next convention city occupying the rest of the session.

The paper by Henry L. Lyon, deputy water commissioner, of Buffalo, contended that the cost per million gallons of water pumped by electrically-driven engines was $1.84, while the steam-driven pumps required $5.22 per million gallons.

Messrs. Will. J. Sando, consulting engineer, Milwaukee; Chas. A. Hague, consulting engineer, New York, and D. W. French, superintendent, Weehawken, N.J., claimed that the experience of Buffalo could not be accepted as a general preposition. It was pointed out that the proximity of Buffalo to the Falls, and the consequent cheapness of electrical power there, weakened the argument in favor of the electrical pumps. In Boston, where coal costs $3.87 a ton, as against $2.50 in Buffalo, equalizing the head pumped against, the price of pumping was only $4, as against $5.22 in Buffalo. Seven municipal and 15 individual pumping stations in the U.S. pump water cheaper than Buffalo, notwithstanding the favorable conditions existing at Buffalo.

Anticipating a lively discussion at the American Waterworks Association on the relative merits of steam and electric pumping, Mr. John McDougall, Caledonian Iron Works Co., Ltd., distributed among the members a bulletin, giving the official test of the three-stage 14-inch Worthington turbine, driven by a 400 h.p. Allis-Chalmers-Bullock motor installed at the McGairsh street pumping station of the Montreal waterworks.

Election of Officers.

Officers were elected as follows:—

Geo. H. Felix, Reading, Pa., president; D. W. French, Hoboken, N.J., 1st vice-president; Dr. William P. Mason, Troy, N.Y., 2nd vice-president; Jerry O'Shaughnessy, Columbus, Ohio, 3rd vice-president; Alexander Milne, St. Catharines, Ont., 4th vice-president; Charles Henderson, Waterloo, Iowa, 5th vice-president; John H. Diven, Charleston, S.C., secretary-treasurer. The finance committee was re-elected.

Next Convention at Washington.

After an exciting time Washington was chosen as the place for the convention in 1908. The cities bidding for this were: Washington, Chicago, Milwaukee, Philadelphia and Atlantic City.

Other papers read and discussed were: High Duty vs. Low Duty Pumping Engines, by Irving H. Reynolds, Youngstown, O.; and, A Peculiar Instance of Contamination of Ground Water, by Wm. P. Mason, Troy, N.Y.

The afternoon was taken up in a trolley ride around the city and to several of the parks. The evening session consisted of interesting illustrated papers on waterworks stations in other countries, given by Allen Hazen, New York, and Geo. A. Johnson, New York.

Flow of Water in Pipes.

The morning and afternoon sessions of the fourth day were taken up in the presentation and discussion of papers, and in the reports of committees. A moonlight excursion, given by the city of Toronto, was much enjoyed by the delegates.

The committee on waterworks standards submitted specifications for cast iron water pipe and special castings. The report, after some discussion, was returned to the committee, who are to report further next year.

Nicholas S. Hill, C.E., of New York, gave a paper on tuberculation and the flow of water in pipes, a subject which he thought had been very much neglected. He arranged the deposits which lessen the carrying capacity of water pipes into three classes—incrustations, growth on the inner surface of iron pipes and accumulations in inverts, hollows and dead ends. He was satisfied that tuberculation would not occur where the iron was protected from contact with the water. Slime, pipe moss and sponge growths were treated from a scientific standpoint, all being dependent on organisms carried in the pipes for their food. Efficient filtration would remove these deposits by starvation. The application of coal tar pitch was considered the best coating ever devised for pipes.

Dr. Geo. F. Whitney, New York, gave a number of experiences in cleaning water mains, showing how great increases in the water pressure had been obtained in various cities.

The question of cleaning water mains was further discussed by C. H. Campbell, of Atlanta, who read the paper of Col. Park Woodward. It stated that water works systems were too often put in with too little provision for the future growth of the town or city. Thus the mains were often too small within a few years but, in many cases, it would be found cheaper to clean them than to lay new ones. A test in Atlanta had shown that the cleansing of the mains had saved the laying of an additional main, the increase in supply being 65 per cent., and the pumping engine showing an increase in delivering capacity of over 45 per cent.

National Water Boards.

The evil effect of allowing political considerations to influence the management of a water works system was presented by Secretary Diven, in a paper on "How can Politics be Eliminated from Municipal Water Works?" He said that long study and practice were required to make a good water works manager, and if the changes in civic administration meant a new man after every election, there was no opportunity of the manager learning his business. He denounced the system whereby ward workers were rewarded by positions for which they were unfit, and favored the appointment of water commissions which would have absolute control of the water works plant and also of the sewage system. These commissioners should elect state boards, and from the latter a national board should be selected to control the inter-state water supply.

Mr. Henry L. Lyon, of Buffalo, gave a paper on a plan for interchange between low and high service systems. The Buffalo water works, he said, were started in 1848 and purchased by the city 20 years later. Now there was a reservoir containing over 116 million gallons, and the daily consumption was 130 million gallons. There were ten pumps, and the necessity of changing these from one service to the other created a problem in taking care of the

distribution pipes, the solution of which was described.

Mr. H. S. Baker, of Chicago, told of the remodeling of the discharge pipes at the Springfield avenue pumping station, where the system was entirely remodeled without interfering with the work of the station. It was done by laying the discharge in consecutive steps, so that at no time were more than two pumps out of service. The present pumping capacity of the Chicago water works was given at 625 million gallons daily.

Mr. Harry A. Lord, of Ogdensburg, described a break in the water main in the bed of the Oswegatchie River, and the means used in repairing it. His paper was read, in Mr. Lord's absence, by the secretary, the writer having been attacked by rheumatism.

Proper Water Rates.

"The Proper Rates for Domestic and Public Service," was the subject of the paper by Mr. John Ericson, of Chicago. He thought that on account of local conditions varying, the rates applicable to several cities could not be averaged to provide a safe basis for charges by any corporation.

Dr. W. P. Mason, of Troy, gave some notes as to the action of water upon lead and zinc, saying that a water user should know what possible damage might result to his supply by reason of its being conveyed through metallic piping. It was shown that water containing traces of zinc had been used for long periods without injurious effects. Mr. R. J. Thomas, of New Lowell, cited a case where 40 cases of poisoning resulted from lead in a driven well.

"The St. Louis Method of Purification," was the subject of an interesting paper by Mr. Wilson F. Montfort, St. Louis, who stated that the water was purified by sedimentation basins. After it passed the first basin the water was fairly well clarified.

Dr. John Galbraith, LL.D., Toronto University, was made honorary member of the association.

Large Number of Papers.

On the closing day of the convention a large number of short papers were presented.

In the paper on "Dowsing," by Mr. Charles Anthony, jr., Bahia Blanca, Argentine Republic, who was not present, it was stated that the action of the "divining rod" was due to radial activity.

"Repairing a Broken Force Main," by Mr. C. W. Wiles, Delaware, Ohio, related the personal experience of the writer, whose chief difficulty in repairing a three or four foot main was that the water was running through the course at the time.

Mr. T. W. Davey, Middletown, N.Y., spoke of "Stripping Reservoir Land, or Some Methods Used for the Prevention of the Growth of Algae."

Other subjects disposed of were:—"Some Personal Waterworks Experiences," Mr. L. N. Case, Duluth; "Some Experiences Met With in the Management of a Small Waterworks Plant," Mr. Howard L. Williams, Luddington, Mich.; "A Wheel Pump," Mr. H. F. Dunham, New York; "The Operation of a Pump While Submerged by Flood," Mr. E. Forest Williams, Du Quesne, Pa.; "Rates and Regulations for Private Fire Protection in Atlanta, Ga.," Mr. Park Woodward, Atlanta; "Special Fire Protection Rates and Regulations, Elmira, N.Y.," Mr. J. W. Dinen, Charleston, S.C.; "Connection From Public Water Supply for Private Fire Protection Service," Mr. A. W. Hardy, Chicago.

Exhibits of Brass Goods.

The only Canadian manufacturers to exhibit were the Jas. Morrison Brass Mfg. Co., and the Canadian Fairbanks Co., both of Toronto. The latter had a small display of valves and other brass goods, while the Morrison Co. had one of the largest exhibits at the convention, showing a full line of their corporation waterworks service brass works, as well as a number of engineers' clocks, recording pressure gauges, etc. Chas. World and A. Betton, Ontario sales representatives, were in charge, and all Canadian delegates were reminded that "Made in Canada" waterworks brass goods could be secured.

The Mueller Mfg. Co., Decatur, Ill., had probably the largest representation of any firm, they being represented by Messrs. Fred. Mueller, Henry Mueller and wife, and H. F. Clark, of Decatur; Oscar Mueller and wife, New York, and R. M. Hastings, Buffalo, N.Y., their Ontario representative. They had a very large exhibit, comprising all classes of water, gas and plumbing brass goods

The Hays Mfg. Co., of Erie, Pa., were represented by C. J. Nagle, the Canadian sales agent of their company, and well-known to the trade throughout Canada. Amongst the leading lines included in their display were the Hays extension service boxes, corporation cocks, lead goose necks, iron body clean outs, and general waterworks and gas

Full Lines on Display.

The Glauber Brass Mfg. Co., of Cleveland, had a nice exhibit in charge of I. Herzbrun, special traveling representative. Their display consisted mostly of waterworks brass goods, a complete line of inverted curb stops and stop and wastes being shown, from the smallest to the largest sizes. Other lines on display were different styles and sizes of corporation cocks, goose-necks for water connection, stop and stop waste cocks for plumbers' use, service and meter cocks for gas companies, and an assortment of compression and fuller work, both brass finished and nickel-plated. "They never leak and they always work easy" is the Glauber motto.

United Brass Mfg. Co., Cleveland, O., was represented by W. J. and S. P. Schoenberger, of Cleveland. They had a similar line of brass goods on the display table, including a number of United lead goose-necks, the joints of which were wiped by the Corcoran wipe joint machine, sold by this company. A demonstration of the splendid work of this machine was also made at one of the departments of the Toronto waterworks. The Messrs. Schoenberger were kept busy explaining the work and system of operation of the wipe joint machine, it creating considerable interest amongst the delegates.

Other exhibitors included the Waterworks Equipment Co., 180 Broadway, New York, lead wool for caulking joints under water; Worthington Pump Co., New York, meters; National Water Main Cleaning Co., 27 William street, New York, iron pipe cleaners; Thompson Meter Co., Brooklyn, N.Y., meters; the Pito Meter Co., New York, testing machines; Neptune Meter Co., New York, meters; Cancos Mfg. Co., Philadelphia, black squadron packing; the Union Water Meter Co., Worcester, Mass., and the Wykoff Supply Co., Elmira, N.Y. The last named company exhibited a section of wooden water pipe bound by metal straps, which had been in service under 30 lbs. of pressure regularly for 42 years.

The Pumping Engine Record.

The world's record for economy and efficiency of waterworks pumping engines is held by the plant at Bissell's Point, St. Louis, Mo., built by Allis-Chalmers Co., of Milwaukee. The duty reached at the official test was 181,068,605 foot pounds. In order that engineers may know exactly how these figures were reached the company printed in bulletin form complete details of the test. These and other bulletins containing information not usually made public, but of great value to those interested in waterworks, were distributed among the members of the American Waterworks Association by Allis-Chalmers-Bullock, Limited, in a handsome souvenir cover.

This firm and the John McDougall Caledonia Iron Works were represented by John S. Maclean.

Learn to hide your aches and pains under a pleasant smile. No one wants to know if you have the earache, headache, or rheumatism.

The Milling Machine Vise

Uses of the Flat and Swivel Vises--Methods of setting jaws of Vises where very accurate work is necessary.

By John Edgar

The character of the work handled on the milling machine makes it necessary to have an effective means of holding the work securely under the heavy strains incidental to the milling operation. That common tool, the vise, is found in several different variations in this service. We find it in several forms, viz.: The flat vise, the swivel vise, the table vise and special vises of several kinds.

Flat Milling Machine Vise.

The flat vise is the one most used and is shown in Fig. 1. The design shown is similar to those placed on the market by several manufacturers, and represents good practice. This vise is of very solid construction, well able to stand the heavy strains of the cut as well as the initial strain necessary to grip the work firmly in the jaws. These vises are very limited in range, which is necessarily the result of compactness and strength. The following table gives the ranges of the commercial sizes now available:

Dimensions of Flat Vises.

Width of jaws.	Depth of jaws.	Jaws open.
5 ins.	1½ ins.	3 ins.
6 "	1⅝ "	3¾ "
7 "	1¾ "	4½ "
8 "	2 "	6 "

These flat vises, as seen, consist of a base, or backjaw (a) and a sliding jaw (b), which is moved by the screw (e), which has a square shank for the use of a crank wrench. The sliding and back jaws are fitted with false or removable jaws of steel which may be substituted by jaws of special shape for special work. The use of these special jaws will be fully explained later.

The uses to which this vise is put are numerous; but before going into its use let us become acquainted with the other forms of vise that are used in milling machine work.

The swivel vise is nothing more than a flat vise mounted on a rotary or swivel base, which may be a component part of the vise or only an attachment making a combination vise that can be used as a flat vise and, when needed, as a rotary or swivel vise. This attachment is merely a circular plate with a circular tee-slot cut in its top for bending the vise in any position by means of tee-bolts. This base is commonly graduated in degrees so that by means of the index mark the vise may be set at any desired angle. This combination makes for most purposes a solid construction, which is not, as a rule, obtained with the ordinary swivel vise, as the former sets lower and offers better opportunity for bolting down the vise in the angular position.

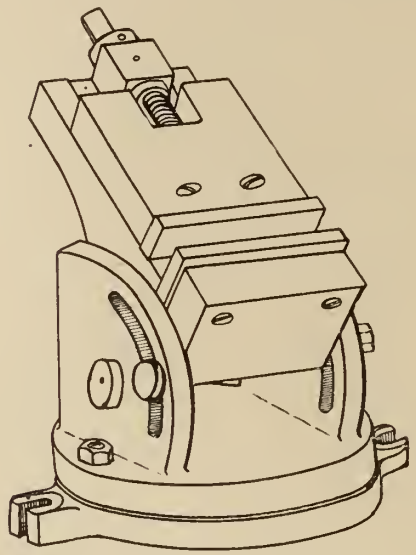

Fig. 2 Universal Toolmaker's Vice.

The flat vise is provided with two slots at right angles to each other, by means of which the vise may be set with the jaws either parallel or at right angles to the arbor. This is accomplished by means of tongues placed in these slots and in the tee-slots of the table. The rotary base is also provided with slots so that it may be always placed in a position relative to the table slots that the graduation marks will coincide with the index mark on the vise itself.

In Fig. 2 we have a special form of swivel vise which has the peculiarity of swivelling in a vertical plane as well as in the horizontal. This vise is much used by toolmakers and comes in handy in making form tools and such work as the toolmaker is constantly running up against. The swivelling movements of this vise are also measured by means of graduations, giving the degree of angular displacement.

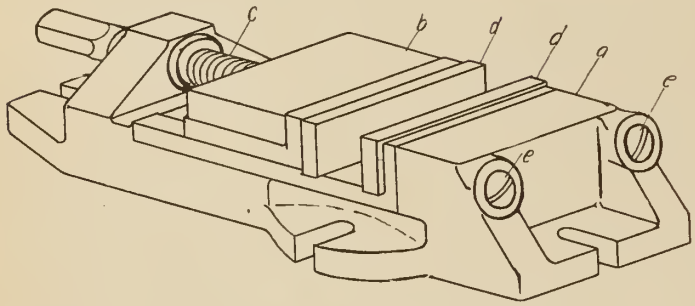

Fig. 1—Plain Flat Milling Machine Vice.

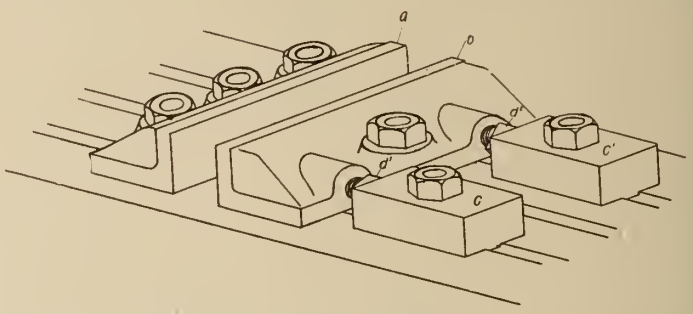

Fig. 3—Table Vice for use on Milling Machine.

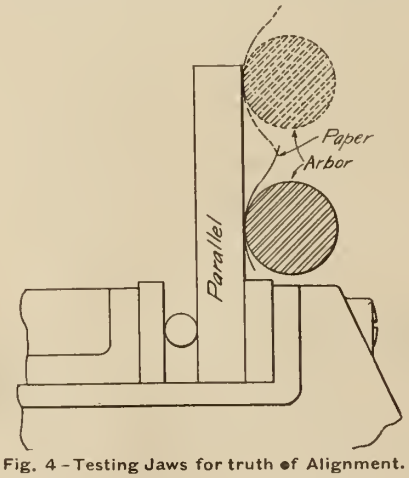

Fig. 4—Testing Jaws for truth of Alignment.

As with the flat vise, this style is also provided with the false jaws, and for the same purpose. Some makers go still farther in the design of the toolmakers vise and provide means by which it is possible to swivel the vise jaws at an angle in the inclined plane. This vise has a greater range of usefulness, but is more expensive and less compact and rigid.

Flat Vise of Great Range.

In order to overcome the limited range encountered in the commercial sizes of the flat vise, the vise shown in Fig. 3 was devised. The range of this vise is only limited by the length of the table of the machine on which

it is used. This table vise consists of two jaws, (a) and (b), and two stops (c) and (c1). The jaw (a) is bolted down to the table securely by the three bolts in the table slots. This jaw is provided with a tongue that engages with the centre slot in the table in order to ensure the face of the jaw being at right angles with the feed of the table. The jaw (b) is made so that it may be fastened to the table in the same manner as the jaw (a) with the exception that but one bolt is used. This jaw is also made so that it may be adjusted by means of the screws (d1) and (d2), which act upon the stop blocks (c) and (c1). It is obvious that this style of vise is only available for holding work lengthwise of the table. It has been most used in connection with the vertical spindle machines.

For Special Work Vises Should be Tested.

It is the aim of the manufacturers of vises for milling machines to produce a tool that is built on "right lines;" that is, with the jaws at right angles with the tongues in the base and at right

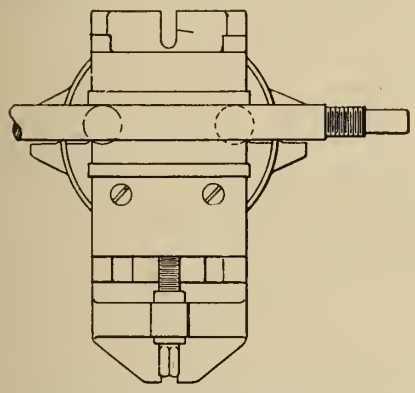

Fig. 5—Setting Vise with Jaws Parallel with the Milling Machine Arbor.

angles in a vertical plane with the base or top of the table on which it sets. Therefore, we may be reasonably safe in accepting a vise that is in fairly good condition as accurate enough for most purposes. When, however, we have a job on hand that calls for a little more care than the ordinary run of such work, it would be best to test the vise in all ways to make sure that the work will not be spoilt through inaccuracies of the vise.

The vertical truth of the jaws may be tested by the method shown in Fig. 4, where (a) is a parallel pinched between the jaws and the round piece of drill rod or other round stock. Now bring the arbor against the parallel in the lowest position and then with the arbor in the same relative position lengthwise of the table drop the knee until the extreme end of the parallel is reached, and if the arbor is still in contact with the parallel and does not press any harder against it in one position than in the other the jaw may be accepted as at right angles with the top of the table. By the use of a piece of thin paper inserted between the arbor and the parallel the pressure between the two may be better tested. This should be tried first on one jaw, then on the other, to make sure that they are parallel. It is more important to have the back jaw right than it is that the sliding or adjustable jaw be so.

In case an inaccuracy is discovered, the jaws may be shimmed up sufficiently to bring them square.

To prove the truth of the jaws in a direction parallel with the spindle we may raise the knee so that the arbor will come into the opening between the jaws with its centre about half-way in the gap, and then by pinching two pieces of thin paper or two other pieces of material of equal thickness between the arbor and the jaw at each end of it we may test the parallelism of one with the other by the "bite" of the two pieces of paper. In this position the index mark of the swivel base, if the vise is a swivel vise, should be at the zero mark on the graduated circle.

Testing Vise for Vertical Miller.

Should the vise be used on a vertical spindle machine the parallelism with the motion of the table or the carriage may be tested by means of a plug placed in the spindle hole, and by the paper test being applied first at one end of the jaw and then at the other, as shown in Fig. 5 by the dotted lines.

To Have Jaws at Right Angles to Axis of Cutter.

Should it be desired to set the vise so that the jaws would be at right angles with the axis of the cutter, we would proceed as in Fig. 6, and by means of the square and the paper test the squareness of the jaws with the centre of the arbor. The dotted circles show how the vertical spindle machine may be used to test the setting of the vise when the square is used.

It is well to remark here that in making these tests with the arbor it must run reasonably true, as much depends on the truth of the arbor for the accuracy of the setting obtained.

These Tests Necessary for Special Tool Making.

As mentioned above, these refinements are very rarely gone into in the use of the milling machine vise, but there are some jobs that the toolmaker has to do that occasionally call for extreme care and skilful handling. In such a case it would be best to remove the tongues from the flat vise, if it is used, and set it by the methods just explained.

To Increase Holding Power of Jaws.

When holding work in the vise jaws, especially where heavy cuts are taken parallel with the jaws, the placing of a strip of paper between the work and the jaws will increase the holding power of the latter considerably, and for most work this will not alter the practical accuracy of the results enough to make any particular difference. The thinner the paper is, the better the results.

In holding round bars or shafting in the vise, the use of a V-block jaw will be found advantageous. When we have a lot of round work of the same diameter to slot or mill in the vise, it will be found advantageous to use a holder made of a block of iron with a hole bored lengthwise and split along one side, so that when passed over the work and held in a vise the work is held securely without in any way marring the surface. Tubing may be held in this way without the danger of crushing it out of shape.

When we have a flat piece of work which requires a milling operation to

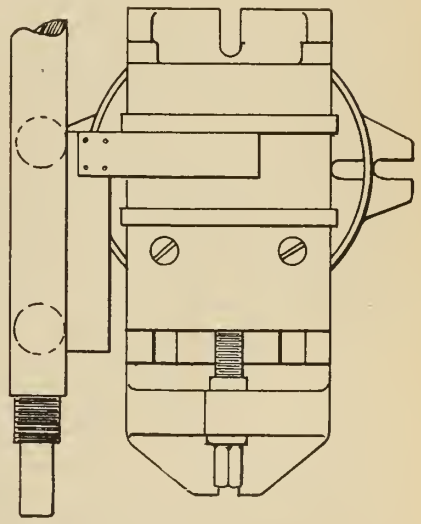

Fig. 6—Setting Vise with Jaws at Right Angles to Milling Machine Arbor.

form the edge it is necessary to hold the work well up to the cutter in order to avoid any chattering, which is inevitable unless it is so supported. This is done by making a set of jaws to follow closely the shape of the cut and substitute them in place of the regular jaws by means of the screws, as mentioned in the foregoing part of the article.

Vise Best Means for Holding Work.

There are other means of holding work on the milling machine, but for work that is of such a size and shape that it is available for holding in the vise, there is no more efficient or effective way of doing so. For quick short cuts the vise offers the best advantages as a holding medium. Some special uses for the vise will be taken up later.

CANADIAN MACHINERY
and Manufacturing News

A monthly newspaper devoted to machinery and manufacturing interests, mechanical and electrical trades, the foundry, technical progress, construction and improvement, and to all users of power developed from steam, gas, electricity, compressed air and water in Canada.

CANADA HANDICAPPED BY LACK OF EXPERIENCE.

An article on the slow growth of the Dominion by a young Canadian now resident in the States, is attracting a great deal of attention, and is being criticized by many of the newspapers.

So far as we have seen the Canadian papers have contented themselves with attacking the New York writer and his theories as to the cause, but none have themselves satisfactorily explained why Canadian progress has been so very slow, why American growth has been so very rapid, and why so large a percentage of our business young men and women have gone to the States, and having gone there, why they have made much greater successes than their equally clever and brainy companions who remained in Canada.

Some of the writer's statements and deductions are absurd, but in the main his article is absolutely true. Until recently Canada has not progressed. The men in Canada who have done things; the Canadians who have gone abroad and done better things and whose opinions are worth while, say that Canada's failure to progress is not due to British connection, which is a great advantage, or to any lack of ability on the part of the Canadians at home, but to a lack of experience, and to the lack of encouragement and inspiration which experience gives.

Many of these writers say that Canada has suffered through lack of capital. Excepting in stringencies such as we have at present, Canada has had all the capital needed for any development on which her citizens have ever found it necessary to embark. Where Canadians have had the experience, encouragement and inspiration to do things, they have been done, and generally done better than in the United States, and the progress has been greater. Take our dairying for example and the industries, such as pork packing, allied with this; we have outclassed the Americans in both quantity and quality. We have done so because we were shown how; we have surpassed those who taught us. We will do the same in many other lines of manufacture.

To succeed Canadians must have the experience, encouragement and inspiration of those who are successful themselves; this can only be got by personal contact or by reading the publications from which these can be gleaned. Yet the Canadian Post Office, by abrogating the postal arrangement with the United States, has done its best to shut out the best trade and technical newspapers, magazines, etc., from which thousands of Canadians have been getting inspiration in the last few years to do things. They have been doing, and the country is growing as it never did before in population and wealth. The best interests of the Dominion require that we have these publications. Our development will suffer from lack of them.

The MacLean newspapers have more to gain than any other concern in Canada by shutting out American publications; yet they have all along taken the broad ground that what was best for the nation was, in the long run, best for them, and if they cannot hold their own field against United States competitors, they do not deserve it.

ENGINEERING COURSES AT WINNIPEG.

Recognizing that the Canadian Northwest will require a large number of men with engineering training to carry on the immense amount of engineering work which will be entailed by the quick growth of the country, the University Council of Manitoba University will organize courses in civil, mechanical, and electrical engineering.

The rapid growth of the Applied Science Faculty of the University of Toronto is ample evidence of the field for such an undertaking by the Manitoba University. At present there are quite a number of students from Western Canada attending science in Toronto. No doubt there will be plenty of material for the new department in the Manitoba University.

In time the University will have the full equipment

required for complete courses. At present it is without even the beginnings of such an equipment. Inasmuch, however, as the first two years in these courses consists mainly of theoretical instruction and drafting work, it is proposed to go ahead at once next October. The whole matter of the equipment of the University for these courses, with shop facilities not merely for forging, but for foundry work and the other necessary practical work, will have to be taken up by the University Commission when it is appointed.

It is thought that arrangements can be made with the machine shops and foundries in the city for the accommodation of the students for practical work.

In embarking upon this new enterprise, the University should secure strong men for the conduct of these new departments. Upon the personnel of the teaching staff will depend to no small extent the success of the venture and the success of the graduating students.

PAPER SHOULD STAND UPON ITS INTRINSIC MERITS.

An expression of opinion as published by "Paper Trade Journal," strikes at the core of the weakness of a good many mechanical and engineering papers as well as trade papers. This paper says :

> "No stronger evidence of the valuelessness of a trade paper as an advertising medium can be presented than that of soliciting advertising upon the strength of sales of machinery or other goods which may be brought about through the influence (?) of the paper's representative. It is at once a frank confession of the lack of the essential qualities upon which the advertising value of any publication must of necessity depend—a bona fide subscription list and that influence which comes through prestige."

Many an advertiser has been practically held up in this way by advertising representatives. In some rare instances the advertiser may secure sufficient graft orders to make the investment worth while ; but that is only the case when the graft has been handed over before the manufacturer signs the advertising order. Once the advertising man has secured his advertising contract his interest in that special case evaporates. A new interest is then taken up, and all the graft is directed into a new channel.

It is absurd to think that implied or expressed promises should result in anything to the manufacturer after his signature to the advertising order has been secured. All inquiries which may come to papers adopting such a policy, will of a surety be used as bait for new advertisers. In the big majority of cases the manufacturer who allows himself to be thus beguiled is badly sold.

There is another thing which must be considered by the manufacturer. "The publication which cannot secure advertising patronage upon its merits is certainly not worth considering." No publisher of reliable papers will permit this graft. It is only the paper which cannot secure and hold its advertisers on the strength of its intrinsic value, that resort to such methods of obtaining advertising orders.

A policy of that kind spells ruin for the paper sooner or later. A sound paper cannot be built upon such an insecure foundation.

Such a paper is useless to the manufacturer as an advertising medium.

MALLEABLE IRON INDUSTRY.

There is not a more busy industry in Canada at the present time than the malleable iron. All the manufacturers of malleable castings have more work on hand than they can handle. Capacities of present plants are being enlarged, and projects for new ones are being formed. The making of malleable castings is a tricky business. Not all heats turn out well, even in experienced plants. To get the carbon in the iron combined chemically to form white iron without getting it hard requires careful mixing and careful manipulation.

In view of these facts, the opinions expressed by Dr. Richard Moldenke in the article, "The Malleable Foundry as a Business Venture," published in the foundry department of this issue, will be of particular interest to Canadian foundrymen and Canadian manufacturers.

Dr. Moldenke is a recognized authority on malleable iron, and his words should carry some conviction. He advises the manufacturer not to establish malleable castings plants unless there is at least five tons of castings to be made daily. He reviews all the considerations which should be taken up before embarking upon such an enterprise, either to supply a manufacturer's own needs or to do a jobbing trade. These considerations are based upon conditions existing in times of prosperity, like the present, and also upon conditions existing when times are bad.

In succeeding issues we will publish similar articles on "The Grey Iron Foundry as a Business Venture," and "The Steel Foundry as a Business Venture," by Thomas D. West and by W. M. Carr, respectively, both men specialists in their lines.

CANADIAN INVESTMENTS IN BRITAIN.

Canada during the next few years will need considerable capital to carry on her enterprises. She will have to look for this capital outside her own Dominion. Great Britain and the United States are the countries chiefly interested. The large percent of the money must come from these countries.

In view of this fact it is interesting to note what Frederic Nichols says concerning the stand British capitalists take in this matter. He has just returned from a visit to the Old Country, and says :

> "The general feeling among British investors is very favorable to Canadian enterprises in view of the fact that their own home railway and South African securities, which have been their favorite investment heretofore, are receiving but scant attention at the present time."

This is well. Already Canadian enterprises are feeling the tightness of money somewhat. Unless the situation is relieved before it becomes more stringent, there may be a reaction, with accompanying bad times. It is gratifying to know that Britain's capitalistic sentiment is in favor of Canadian investment.

Suction Gas: Its Manufacture and Use

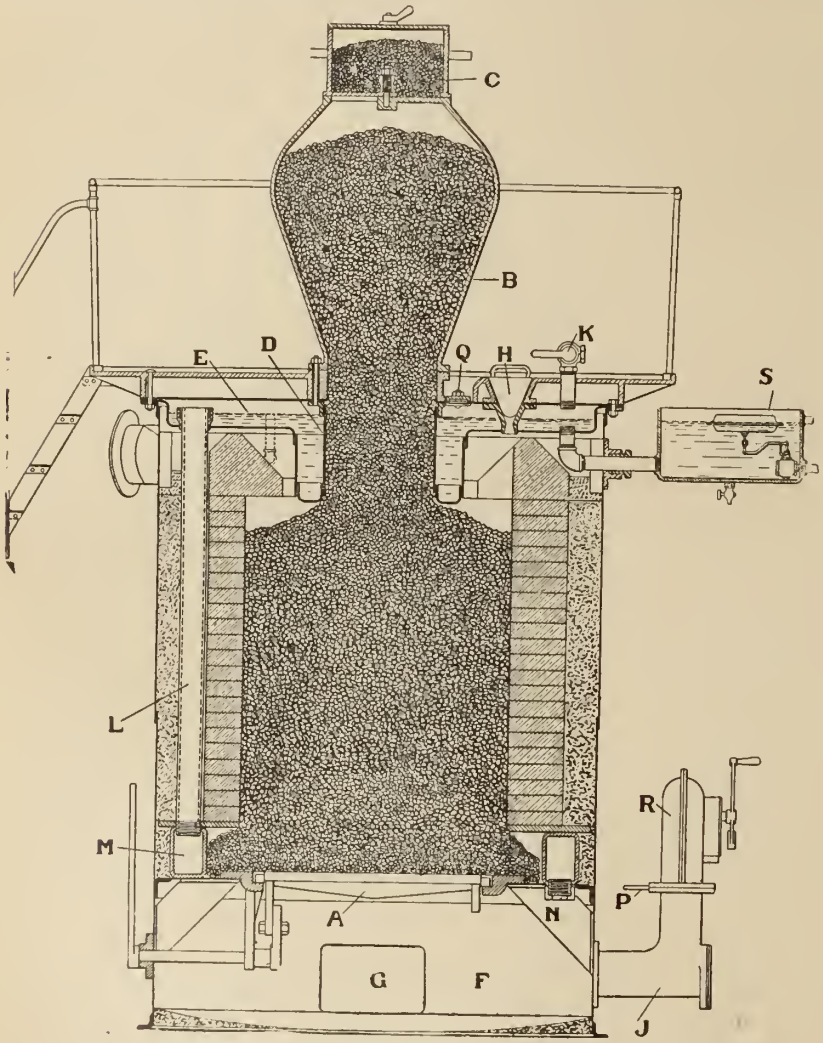
ECONOMY OBTAINED IN SMALL PLANT INSTALLED IN FLOUR MILL UNDER OPERATING CONDITIONS.

Article III. By Emil Stern.

The two articles on suction gas in the October and December, 1906, issues of this paper dealt largely in a descriptive way with the subject. The first article showed general features of these plants; while the latter described a number of individual plants as made by modern manufacturers.

The purpose of this article is to draw conclusions from the two preceding ones.

It can safely be said that in the course of the next few years Canada will see a fight between ancient and modern prime moving systems, as all the European countries have seen, Germany first, France and England following. On this continent the riches of the natural sources of power have delayed the development of gas producers for some time. The United States first started to develop them, and recently some Canadian manufacturers have started to build gas producers, some of them trying their own design, others adopting the safer way of manufacturing under a license and from drawings of old established European firms, thus securing for the Canadian buyer the advantages of home-made goods, as well as the advantage of well tried systems, the reliability of which has been proven by years of experience.



A Style of Suction Plant with Internal Vaporizer.

Economy of Suction Plants.

If we try to find out what has made the suction gas producer such a complete success we find that many points have to be considered, chiefly economy.

The manufacturer has several ways of obtaining power. The easiest way, the most expensive, too, is to buy the power from a central station, installing an electric motor and paying 2½c. or more per b.h.p. hour, which totals up to $75 per year, (3,000 hours for one b.h.p.). The gasoline engine in the country does not stand much better.

Recently the writer saw a gas power installation that, better than all scientific explanations, shows the superiority of the gas producer in all cases where power is required for any length of time. I do not include in this consideration small power installations required only one or two hours every few days. In these cases, and similar ones, city gas, gasoline or central station electric power are much more suitable, as the fuel economy would be greatly decreased by the stand-by losses. The case I am referring to is that of a chopping mill equipped with an 11-inch blade feed chopper in a small town in Ontario where no power was available from the town. A miller decided to put in a 35 h.p. gasoline engine, which worked quite satisfactorily as far as just the working was concerned; but when the miller compared his expenses with the incoming money he found that nothing was left for him. This average daily result was:

Incoming money—	
250 bags at 5c.	$ 12.50
Expenses—	
Gasoline, 30 gals. at 25c.	$ 7.50
Help	1.25
Lunch for two	1.00
Oil and waste	.25
	$10.00

This left $2.50 for himself, not figuring on rent, insurance, interest and depreciation. This result was so discouraging that he at last stopped the mill altogether. However, a Toronto firm installed for him a suction gas producer to run his old gasoline engine; the result is as follows: The capacity of his engine was decreased from 250 bags a day to 200 bags. This is accounted for by the fact that producer gas, being a less rich gas than that produced from gasoline, requires a larger engine for the same power.

Incoming money—	
200 bags at 5c.	$10.00
Expenses—	
Hard coal, 400 lbs. at $5 per ton	$ 1,00
Help	1.25
Lunch for two	1,00
Oil and waste	.25
	$3.50

This leaves a profit of $6.50 a day, a satisfactory figure for the size of the mill. Comparing the figures for gasoline and suction gas it is evident that gasoline as a fuel costs six times as much, or 500 per cent. more, than suction gas.

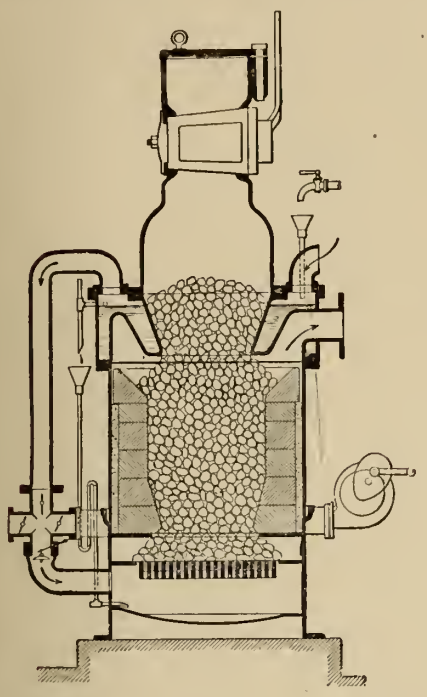
According to the above statement rela-

tive costs are as follows :

To chop 1 bag of feed with gasoline 3c

To chop 1 bag of feed with suction gas .... ½c

These figures are for a small plant, and are taken from the results of actual running for several months, and not

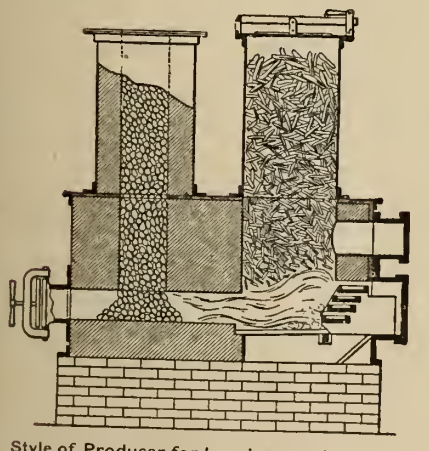


Producer with Internal Vaporizer, and with Cock Valve in Hopper.

from a short test, which is always liable to be somewhat out.

Suction Plant Pays for Itself in Two Years.

It is a fact that a producer gas power installation will pay for itself within two years, even at an initial cost of



Style of Producer for burning wood fuel—the Riche Combustion Producer.

$50 per b.h.p. for large plants, and as high as $100 per b.h.p. for small plants.

Central Stations Will Install Producer Gas Plants.

It is said that after a while the only way in which the large central electric stations can be made to pay will be to install producer gas plants and do away with their present steam plants. Then the selling price per kilo-watt could be reduced, and all power users could derive profit from this more economical way of generating power.

Better Utilization of Heat in Gas Plant Than in Steam Plant.

The economy of the gas producer in connection with the gas engine depends altogether upon the better utilization of the heat contained in the coal. A steam boiler and engine plant does not utilize more than 6 to 18 per cent. of the heat energy contained in the coal. A producer gas and gas engine plant, on the other hand, turns 20 to 33 per cent. of the heat contained in the coal into mechanical energy. We can easily imagine the reason for this poor economy, with steam as compared with producer gas, when we consider that with the gas engine, one medium is done away with altogether. When we put coal in our steam boiler and ignite it, gas is generated and burned above the coal, heating and vaporizing the water for use in the engines. To make suction gas, coal is used in the same way, but instead of the gas being burned under the boiler to produce steam, it is taken to the gas engine and burned there directly. The combustion in the engine is practically a complete one, and thus smoke is eliminated. This, in my idea, is the greatest consideration of all, meaning the saving of national wealth represented in unburnt coal, and the doing away with the ugliest feature of all our cities, the black cloud of smoke hanging over them, carrying dirt and sickness.

PERSONAL MENTION.

Mr. P. A. Kerr, formerly of the Peterboro Shovel and Tool Company, has been appointed superintendent of the Otonabee Power Co., of the same place.

J. Hutton and C. Harris, of the C.P.R. engineering staff on the construction of the Guelph and Goderich Railway, have left Goderich, Ont., for China, where they will be engaged on railway survey work.

Dr. R. K. McClung, who has been senior demonstrator in physics in McGill University, Montreal, for the past three years, has been appointed professor of physics in Mount Allison University, Sackville, N.B.

Chas. H. Danser, who has for the past two years been chief engineer of the Provincial Public Works Department of Manitoba, has been appointed deputy minister of that department. He will still retain the position of chief engineer in connection with his position as deputy minister.

Mr. Thomas MacFarlane, Dominion analyst, who was shortly to retire from public service, died very suddenly this month in Ottawa. The deceased was one of the most eminent analytical chemists in Canada, and had been in the public service for over 25 years. Prior to coming to Canada he was a mining engineer in Norway.

S. H. Jones, president of the St. Thomas Brass Co., St. Thomas, Ont.; the Canadian Bronze Co., Montreal, and the Northwestern Brass Co., Winnipeg, has removed his headquarters from Buffalo, N.Y., to 2 Rector street, New York City. The Magnus Metal Co., which has its headquarters in Buffalo, and of which Mr. Jones is general manager, has sold out to the National Lead Co., a Guggenheimer concern, and its headquarters are now 111 Broadway, New York.

Mr. W. E. Richardson has resigned his position as general superintendent of erection for the Westinghouse Machine Co., to take charge of the Sight Feed Oil Pump Co.'s business at Milwaukee. Mr. Richardson, who is president of this company and inventor of the oil pumps they manufacture, was for sixteen years in the employ of the Allis-Chalmers Co., and has for the past two years been with the Westinghouse Co., in charge of the erection of all the engines, turbines, etc., made by them. A very wide circle of friends in engineering fields will be interested to learn of the Oil Pump Co.'s good fortune.

WISHES WATER POWER PLANT EQUIPMENT.

As an indication of how Canadian Machinery is consulted when manufacturers are installing new machinery and equipment, the following letter from H. Corby Distillery Co., Ltd., Belleville, Ont., is presented :

Belleville, Ont., June 20th, 1907.

The Canadian Machinery,
10 Front St. E.,
Toronto.

Dear Sirs,—Will you please let me have a copy of your paper.

Owing to our recent fire, we are compelled to install a new water power plant, and wish to get the names of the firms who supply the necessary equipment. Yours truly,

H. CORBY DISTILLERY CO., LTD.

It is probable that before long the wooden telegraph pole will be replaced by the concrete. The average life of a wooden pole is seven years; whereas the concrete pole lasts indefinitely.

According to the Ironmonger, Mr. E. L. Rinmann, of the University of Upsala, claims to have discovered a new process for the electrical extraction of aluminium from blue clay, by which the cost of production is reduced to about one-quarter of the present rate.

How an Apprentice Became Superintendent

Boy Started Mechanical Career at Fourteen and is Superintendent of Large Plant at Thirty two Diligent Reading and Steady Work along a Special Line Brought Success.

Man is the architect of his own career. Few are not themselves responsible for their success or failure. Upon the surface some appear handicapped in the fight ; but when conditions are analyzed completely the supposed handicap is often found a help.

Determination to succeed, perserverence in carrying out plans, and good hard work along specialized lines are significant of success.

There is inspiration for the young fellow starting at the hottom in the fact that very many men occupying important positions and drawing large salaries have been there before him.

The bottom is a good place to start. One is then personally acquainted with all the rungs of the success ladder, from the bottom up. A great thing, this personal acquaintance !

"Ever since a youngster, I have been determined to succeed. I never lost sight of this object. I read everything I could lay my eyes on. I never went back on a job. My motto was and is : 'Anything that can be done, I can do!' This refers to my special line. Outside of that I am not an authority, I must take for granted what other men say."

This is what Mr. A. Grass, superintendent for Whitman & Barnes Mfg. Co., St. Catharines, Ont., says concerning the means of his advancement from an apprentice to the position he now holds. Grass' experiences are ample evidenee of how perseverence can make fortune smile He has done what any other young mechanic can do, if he sets his mind on it and works with everlasting perseverence.

Grass started his career as a mechanic when a lad of fourteen years in wiring baled hay. Later he ran the engine used in this work. That early he showed the spirit of progress. His liking for mechanical work led him to start as an apprentice in a marine machine shop in St. Catharines. It was while there that he took to reading mechanical papers. He was not satisfied with one or two, hut read many. That early in life he realized the importance of speeializing. He was much interested in the making and using of dies. He studied their construction ; he studied their use. He read everything he came across concerning them. Result ! He is now works superintendent of a large plant where the forging of tools is the chief work.

From the place of his apprenticeship, Grass went to Thorold to undertake hlanking die work for bicycle works. That class of die work did not appeal to him, and he did not remain long. He went to Whitman & Barnes, getting the position because of his knowledge of die work. There he proved himself. His undertakings were successful. He knew about die work. He had ideas, and carried them out. There was a place for such a man. He was made superintendent.

Nor has it taken a lifetime to do this. Grass is now only thirty-two.

The boy as an apprentice saw in himself the man as a superintendent. He had faith in himself and in his possibilities. He succeeded.

This man started out with a very slight education. His start in life was the one he gave himself. His opportunities were those he made for himself. One would say that he was handicapped. But in this case, as in many others, the handicap did not hold the man down. He himself attributes his success to specializing along one line, to keen observation of everything he saw, to close reading of matter pertaining to his special work in all mechanical papers he could obtain, and to his perseverence in carrying work to a successful issue. He says, not in a boasting, but in a matter-of-fact way, that he has never been floored by a job ; and he has had some difficult propositions thrown at him.

Grass has the power of concentrating his mind on a problem ; and now he is often to be seen in his office lying hack in his chair with his feet on the desk, staring into vacancy. He is thinking.

Grass has trained himself not to worry. If something goes wrong in the plant, causing considerable loss, he does not worry. But he, at the same time, sees that it cannot occur again.

REPORT OF NORTHERN WATER POWERS.

The fifth report of the Hydro-electric Power Commission, dealing with the Algoma, Thunder Bay and Rainy River districts, was made public the other day. The areas north of the height of land are not dealt with in the report owing to the sparseness of the population and the lack of demand for power there. These may be dealt with later when the construction of the Transcontinental and the extension of the Temiskaming & Northern Ontario Railways are accomplished facts. In reference to the Algoma and Thunder Bay districts the report says the Spanish, Vermilion and Mississauga rivers, flowing into Lake Huron along the north shore, "are the most important as regards size and hydro-eleetric possibilities, numerous water powers admitting of more or less economical development existing on these rivers." Along the north shore of Lake Superior there are many fine water powers with, at present, little economic value, the Nepigon, Kaministiquia and Current Rivers being the exception. This is due to their being within "transmission distance of the rapidly increasing power markets of Fort William and Port Arthur, and, especially in the case of the Nepigon, being of sufficient extent to use for grinding the pulp output of the Nepigon watershed."

Some details are given of the power developments now in existence in the two districts named. In this connection it is stated that at the Canada Copper Company's power station at Turbine, on the Spanish River, which transmits to the company's plant at Copper Cliff, has a capacity of 5,400 horse power, and additional units are to be installed this year to bring the capacity up to 10,800 horse power in all. The Kaministiquia Power Company's plant at Kakabeka Falls, on the Kaministiquia River, has, the report says, a partial installation of 10,000 horse power, which is shortly to be doubled.

Three prineipal transmission schemes are assumed as best meeting the present and probable future power requirements for a number of points, namely, a line from Dog Lake to Port Arthur, Fort William and vicinity; a line from Cameron Rapids on the Nepigon, to Port Arthur, Fort William and vicinity; a line from the Slate Falls, on the Mississauga, to Thessalon and Bruce Mines. Some of the estimated figures as to cost for power delivered to the sub-stations, ready for distribution, are: At Port Arthur for 12,382 horse power, $9.10; for half the quantity named, $12.60 per horse power per annum for twenty-four hour power. At Bruce Mines from Slate Falls for 3,300 horse power, $14.72, and for half the quantity $22 per horse power. At Thessalon, from Slate Falls. 150 horse power $27.10, and for half the quantity $30.92 per horse power.

Of Rainy River the report says: "This district is probably the most copiously watered of any in the province, water powers being abundant, and in many cases of considerable magnitude." The whole of it is embraced by one drainage area, "being part of an immense system, the run-off of which reaches tide-water in Hudson's Bay by way of Winnipeg River, Lake Winnipeg and the Nelson River." The town of Kenora is the only power market in the district at the present time. Fort Frances, owing to its geographical situation as a border town, and to the hydraulic possibilities of the Conchiching Falls, "will doubtless play an important part in the future industrial development of the district."

Development of a Crude Oil Engine

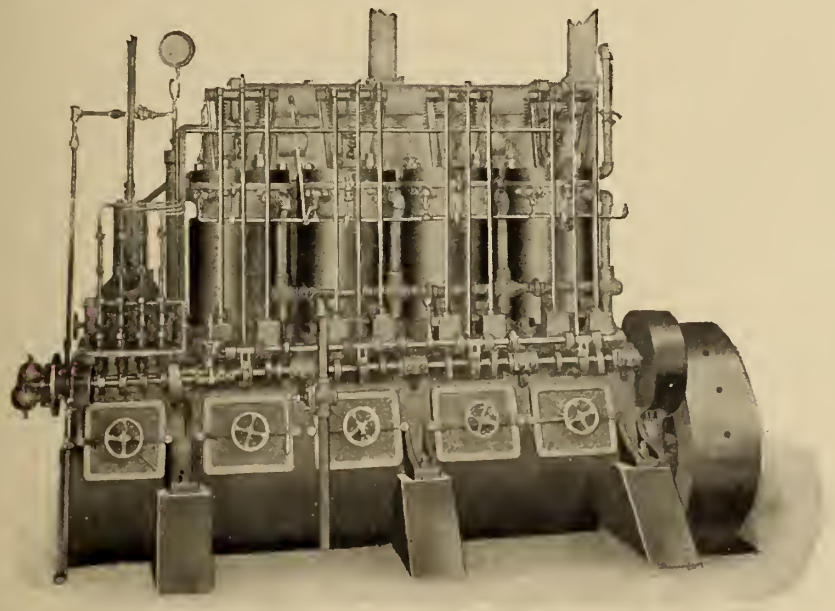
A concise history of how the writer solved the many problems in developing his idea of an internal combustion engine to operate on orude oil — Radically new ideas worked out, absolute failures at first, but finally developed in a commercially successful engine.

By H. Addison Johnston

Among the more important reasons for the low "commereial efficieney" or "power per dollar ratio" attained by the present well-known types of liquid fuel internal combustion motors, a few may be briefly stated as follows :

1. A refined produet is used for fuel.
2. A large percentage of the heat developed by the combustion of the fuel is absorbed by the water jacket and thus lost.
3. The limit of allowable compression pressures is very low, due to the danger of pre-ignition of the mixed air and gas during compression.
4. The lowering of compression pressures in throttle governing engines, when running under full load, increases the fuel consumption.

Other serious defects in the ordinary systems are due, first, to the electric ignition devices being complicated and liable to disorder, and second, to the carburetors or equivalent mechanisms being uncertain and failing to give correct mixtures under variable loads, or when starting the engines.



The Johnston Crude Oil Engine.

The problem, then, as it presented itself to me, was, to discover what new features could be devised, and what old devices eliminated, so that the resulting product would be an engine which would, as far as possible, be subject to none of the undesirable features mentioned above.

It was evident to me that if all grades of heavy unrefined oils were to be used, a vaporizing system would be of no use, as a large percentage of the constituents of heavy oils will not vaporize, but merely form a thick deposit of tar and earbon in the vaporizing chamber. Hence some other system had to be devised.

Having had some experience with oil furnaees for heating steel in whieh heavy crude oil was broken up into a fine spray with compressed air, and in that state completely burned, with no sign of residue, I was firmly eonvinced that just as perfect combustion would take place in an engine cylinder under proper conditions.

Reducing Water Jacket Losses.

The only method of reducing the water jacket loss, seemed to lie in the use of a combustion chamber and cylinder that needed no water jacket, but it was plainly apparent that if the cooling system were eliminated, the charge would reach a very high temperature during compression, and hence the fuel and the air should not be allowed to come into contaet until the moment for ignition had arrived.

Mathematically, the requirements would call for the walls of the combustion chamber to be of a non-conducting material, with no capacity to retain heat ; but as far as the writer's present knowledge extends, no heat insulating or non-conducting material has been found, which will serve for the interior lining of a eylinder, though many experiments have been made for the purpose of finding one. Hence it has been necessary to fall back to the engine's old stand-by, cast iron, and to use an as-

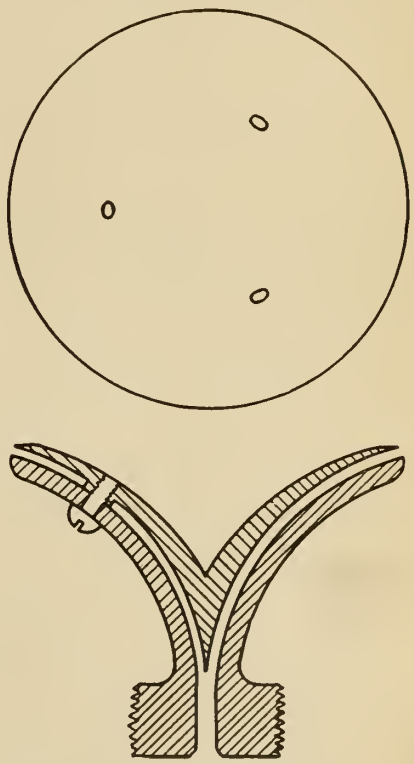


Fig. 2—Johnston Crude Oil Engine.

bestos packing to prevent the eseape of heat.

This descent from the theoretical, ideal chamber, with non-conducting walls, to the practical cast iron asbestos-packed cylinder, is one of the many approximations that have to be adopted in working out our mathematical equations with commercial materials.

The iron absorbs a eertain amount of heat from the burning charge, which it gives out to the sueeeeding fresh charges and thus in a small degree detracts from our theoretical efficieney ; but, as will be shown later, this works out to the general benefit of the proposition.

Consideration of Limitations in Compression.

The limits noted as to the degree of compression allowable in the ordinary gas engine eycle would cease to apply in the new eycle if the fuel and air were

not to be in contact during compression.

If then, the fuel and air were not to be in contact during compression and the combustion must take place before expansion, the fuel must be injected at the end of the compression stroke and be ignited immediately.

Ignition and Vaporizing Solved.

The question of ignition has now solved itself to a certain extent. After the engine was warm and running there would be sufficient heat retained from the previous charge to ignite the fresh fuel immediately when injected.

As the fuel was now to be injected in-

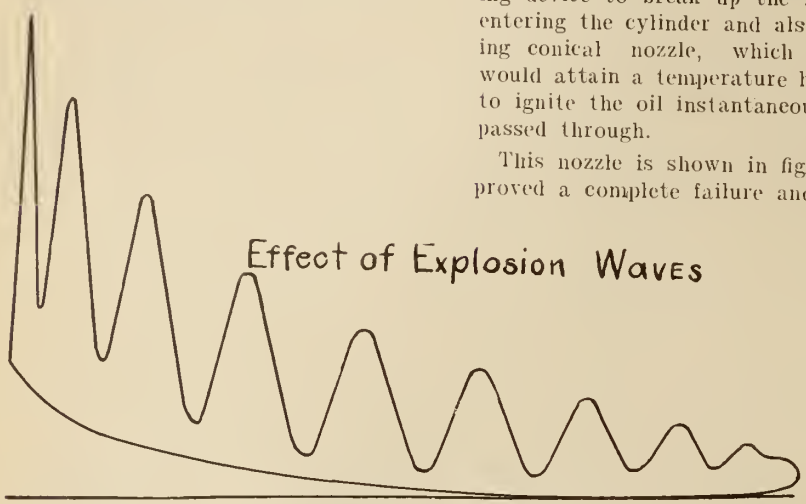

Fig. 3—Johnston Crude Oil Engine Card.

to the already compressed air, and burned, instead of being vaporized, mixed and exploded ; the matter of vaporizers, or carburetors, needed no attention and the only requisite was a pump which would automatically measure and deliver to the engine at the proper time each working stroke, the quantity of oil required by the load.

As there is no explosive mixture question to consider, the air supply does not need to be regulated with the oil, and hence the compression pressure will remain practically constant.

An Experimental Engine Built.

After working out these ideas, to demonstrate their value, it was necessary to construct an engine embodying them. I, therefore, made complete working drawings for an 8-in. x 8-in. engine, and set out to find capital for building the machine. After a very great deal of trouble and the lapse of several months, I secured what I estimated would be a sufficient amount of capital to construct the engine and try out the principles involved. But, as is usual in experimental work, the original amount raised proved quite insufficient and a further considerable sum of money was expended before the success of the invention was assured.

Figure 1 is a sectional elevation of the engine as originally designed, while Fig. 5 shows the construction now used.

Though it was originally intended to operate the engine on a two-stroke cycle, compressing the air charge alone to its full compression pressure in the crank end of the cylinder, the mechanical difficulties in working out this cycle were so serious that it was decided to omit the feature of preliminary compression and to arrange the engine to work on an ordinary four-stroke cycle.

Experimental Work in Spraying Devices.

I had designed a compressed air spraying device to break up the fuel before entering the cylinder and also a diverging conical nozzle, which I expected would attain a temperature high enough to ignite the oil instantaneously as it passed through.

This nozzle is shown in figure 2. It proved a complete failure and was the

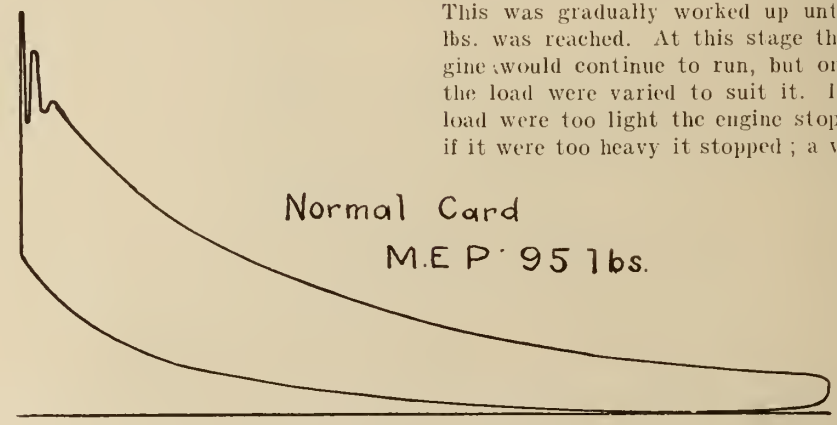

Fig. 4 Johnston Crude Oil Engine.

first of a long series of devices intended to be attached to the cylinder head in front of the injected fuel, to cause ignition and distribution of the fuel.

The method of trying out these devices was as follows : A jump spark plug was inserted in the cylinder head, and the necessary electric connections made, gasoline was fed into the air supply pipe and the engine started up by hand on gasoline.

After a few minutes' running the ignition became automatic and the spark was shut off. The point of ignition gradually advanced as the internal ignition devices became hotter, until it was much too early and caused pounding. The peculiar fact was discovered that if more gasoline was now turned on, the pounding ceased entirely, and by feeding a heavy excess of gasoline, the engine could be run until the lighter parts of the interior of the cylinder showed red hot.

During the latter part of these runs on gasoline, the exhaust was as black as the smoke from a fresh-fired locomotive. When the temperature became so high that we could no longer run on gasoline, the oil was turned on, through the sprayer.

For two months the engine would not continue running five minutes after the gasoline was shut off.

Much time was spent at this period in experimenting with different substances for the interior lining of the cylinder ; but no non-metallic substance could be found suitable for the work.

Sprayers were tried by the dozen, all the ignition devices that ingenuity could contrive. At last by a process of elimination, certain forms were found to be more favorable than others, certain natural laws made themselves apparent, and were gradually formulated, thus establishing guiding lines for future experiments.

Difficulties Met with in Operating Engine and Change of Design.

The first indicator cards showed a mean effective pressure of only 10 lbs. This was gradually worked up until 41 lbs. was reached. At this stage the engine would continue to run, but only if the load were varied to suit it. If the load were too light the engine stopped ; if it were too heavy it stopped ; a variation of the load, ten or fifteen per cent. either way, resulted in a stoppage.

At this time it was decided to make considerable changes in the design of the cylinder and combustion chamber. A new air pump was also built. The m.e.p. was then worked up to 78 lbs. My theoretical card had shown 101 lbs., so further experiments were necessary. Another long period of trying-out followed. The m.e.p. rose by small steps until 95 lbs. was reached. This is as high as is now reached in average work, though individual cards are sometimes obtained up to 105 lbs. The highest card ever

obtained from the engine showed 120 lbs. m.e.p.

Difficulty in Making Engine Run on Light Load.

During all this period of development, the engine would never run on a very light load. If the load were thrown off while the engine was running, it would very soon begin to pound, the pounding in a very few minutes becoming so severe, as to make it advisable to shut off the oil. If it were not shut off, the engine stopped after a few minutes in any case.

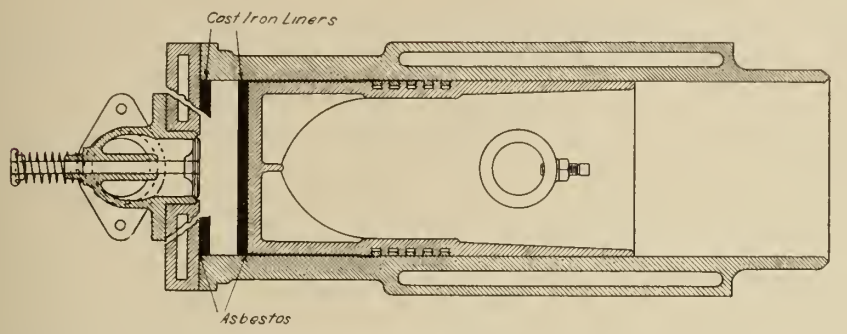

FIG. 5.—This cut shows the construction now used on cylinders up to 12-inches in diameter. It will be noted that while no water-jacketed surface is presented to the burning charge, the part of cylinder in which the rings run is kept cool. On full load the temperatures of the cast iron liners approach a low red heat, but as they do not touch any part except those to which they are fastened, and do not have to stand any strain, no harm results.

Over eighteen months elapsed between the time when the engine first ran on oil and the time when it could be started and run on no load. The engine may now be started and run for any period on no load and yet will take care of full load if thrown on at any time.

Trouble With Explosion Waves in Cylinder.

While the no-load difficulty was bad enough, the worst trouble was due to explosion waves forming in the cylinder. This trouble did not show itself until after the m.e.p. had been worked up to about 50 lbs. The external evidence of these explosion waves was a pound in the cylinder, varying from a mild thump, which could easily be mistaken for a loose bearing on the shaft or rod, to a terrible metallic bang, which sounded as if the whole engine was being pounded to pieces with a steam hammer. The violence of these waves was so great, that in many cases the pencil lead in the indicator would be snapped off on each side of the holder, immediately when the cock was opened.

Figure 3 is a reproduction of a card, showing the effect of the waves on an indicator card, while figure 4 shows the shape of normal cards.

It has taken two years of the most tedious and discouraging work to find out why these waves are formed and how to prevent them forming. It is now possible to design engines so that explosion waves will not form; but the chance of a designer striking the right combination accidentally is less than one in a thousand.

It has generally been the opinion among gas engine experts that explosion waves are largely due to pockets in the combustion chamber, but in all engines experimented with, there have been no pockets of any kind. Neither, as may seem strange to those accustomed to gas engines, does the time of injection of the fuel make very much difference, the waves form apparantly almost as easily when the fuel is injected after the crank is past the centre as when it is before it.

No Accumulation of Tar from Use of Crude Oil.

The principal cause of failure of the previous attempts to use crude oil, or crude residues, in an internal combustion engine, lies in the tendency of tar and other carbonaceous material to accumulate in the vaporizers, cylinders, valve chambers, and other parts of the mechanism. It was freely predicted by those in authority that the Johnston oil engine would be subject to the same difficulties; and among all the experts to whom the proposition was submitted in the beginning, the number who at all appreciated the advantages of the new system could be counted on the fingers of one hand.

In over three years of constant experimental work, there has never been the slightest trouble from this cause, though every kind of cheap heavy oil that could be obtained has been tested in the engine.

The whole of the fuel is absolutely burned and the exhaust is clear and colorless if the engine is properly adjusted and not overloaded. It was found that a considerable overload may be carried, if an extra large supply of oil is fed; the exhaust under these circumstances is quite brown, but there is never the least tendency for deposits to form anywhere in the system.

Grades of Oil Used in Engine.

About 90 per cent. of the oil used in our tests is a fuel oil, supplied by a Canadian oil company. It is a residue from crude oil, after the gasoline, benzine, distillates and kerosene have been extracted and thus is the cheapest of any obtainable fuel.

It was a dark, greenish black in color. The specific gravity is about .875 flash point, and open test 170 degrees F.

The engine has been run on crude oil from Texas, crude oil from Petrolea, cheap fuel oil from anywhere bought in the open market, kerosene, benzine and gasoline. No adjustments in the engine are necessary in changing from one fuel to another, nor is there any appreciable difference in the number of gallons of the different fuels required to produce a given amount of power.

The first tests of fuel economy showed a consumption of 1¼ gallons per 10 h.p. hours, about six months later, 1 gallon.

The consumption now guaranteed by

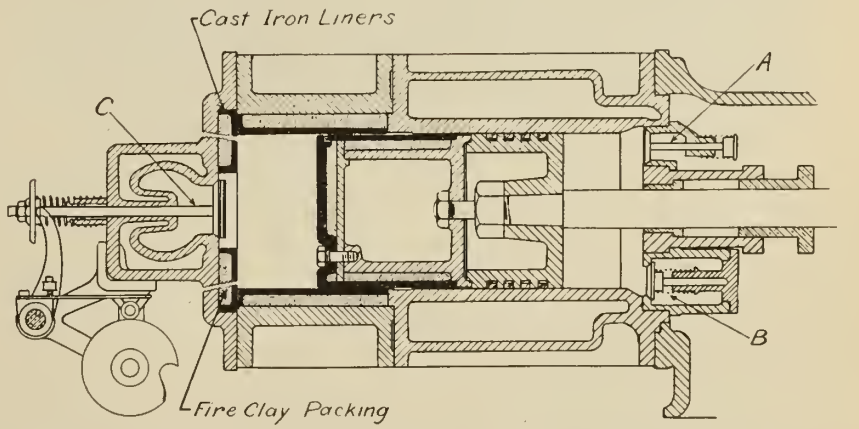

FIG. 1.—This cut shows the engine as originally designed. The air charge was to be taken into the crank end of the cylinder through the valve (A), compressed to 150 lbs. on the return stroke of the piston and discharged through the valve (B) into a reservoir not shown. From the reservoir a pipe extended to the valve (C), and just before the piston started on the working stroke the valve (C) opened and allowed the compressed air to enter the working cylinder. After the cylinder had received its full charge of air the oil was to be injected in a spray and ignited immediately. Owing to mechanical difficulties this system was not used and the engine was run on an ordinary four-stroke cycle.

the Johnston Oil Engine Co., Ltd., of Toronto, Canada, on their 9-in. x 12-in. engine is ¾-gallon of any petroleum product per 10 h.p. hours. The best test or record to date is a consumption of 3-3 gallons per 10 h.p. hours.

Governing of Engine.

The speed regulation is very simply worked out. As no particular proportions of oil and air are required, no explosive mixture being formed, but the oil being simply burned, it is necessary to control only the quantity of oil injected per working stroke, while the air supply may be left constant. The oil pump is controlled by the governor and measures out each charge of oil to suit the load.

Any type of governor may be used, and as the movement of a small cam, ¼ of an inch, is the total motion necessary for complete control, the speed variation can be reduced to a very low percentage.

Starting the Engine.

As noted above, the original method of starting the engine was to use a gasoline explosive mixture, and an electric spark, continuing to run on gasoline until the combustion chamber was hot. There were several serious objections to this method, the principal one being the extremely violent pre-ignition explosions, which occurred just after the gasoline was shut off. As explained before, when running to heat up the engine, it was necessary to feed a great excess of gasoline, to prevent pre-ignition. When the gasoline was shut off, the proportion of gasoline to air fell rapidly with each succeeding stroke, and when the mixture became approximately correct, the resulting explosions occurring at the latter part of the compression stroke, were simply terrific.

The original intention had been to heat the interior of the combustion chamber, in starting, with a plumber's torch, and after the experimental work had progressed sufficiently, so that there was a reasonable possibility of the engine starting when turned over, the torch was used to raise the parts to the temperature necessary for the ignition of the first charge.

This method was fairly satisfactory, but it had the disadvantage that it was necessary to remove the torch from the cylinder, and plug the opening before the engine could be started. If the least time were lost in putting in the plug, or in getting the engine turned over, the parts would be cooled off, and the whole routine had to be gone through again.

After a considerable number of devices had been tried out, the "thimble" starting ignitor, such as is now used, was evolved. As the name indicates, this device is in the form of a thimble and is about one inch in diameter. It is secured to the engine in such a position, that some of the oil, as it is injected into the cylinder, strikes the interior walls of the thimble.

In starting the engine, the flame of a torch is played upon the exterior of the thimble, until it is red hot, the time required averaging three minutes. The engine is then started and the torch is removed afterwards. This method is perfectly reliable and is better than any other for inexperienced operators.

As it was necessary to equip every engine with a compressor, to pump air for spraying the oil, the use of compressed air for starting naturally suggested itself. This starting mechanism was very easily worked out for the second engine, and all engines now built are supplied with an extra air tank for starting. The starting tank may be pumped up to any desired point while the engine is running, and will hold its pressure indefinitely.

To start, it is only necessary to open a valve and move a small lever. The absolute certainty with which an engine of this type will start, is a feature which appeals most strongly to gas engineers.

There are only three conditions to be fulfilled, to make the starting of one of these engines certain, and these conditions are such that it is possible to determine them beforehand. It is not necessary to try to start to see whether the conditions are correct.

The three conditions are: There must be at least 200 lbs. air pressure in the tanks; there must be oil in the sprayer, and the thimble must be red hot.

There is a pressure gauge on the tank; there is a try-cock on the oil line; when the thimble looks red it is hot enough.

The latest achievement in connection with the engine is the successful application of the jump spark for starting. This is the only heavy oil engine in the world, which can be started cold, with a sparker. The ordinary jump spark plug will not fire the oil, but by combining a little theory with a whole lot of practice, one has been designed which will do the work.

The current is usually left on for two or three minutes when starting, after which the engine is hot enough to run without it.

The Engine as it is Now.

To sum up the matter in a few words, the engine is now commercially perfect.

It will operate on any liquid fuel.

It is not subject to either ignition or carburetor troubles.

It is self-starting and reliable.

No part of the engine is subject to deterioration, with the possible exception of the ignitor, which may have to be renewed, in from six to twelve months, at a cost of a few cents.

For marine work, a compressed air reverse is fitted, which is absolutely certain and positive in action.

These engines are now being built commercially by the Johnston Oil Engine Co., Ltd., in Toronto, Canada, and it is expected that arrangements will soon be made for their manufacture in the United States.

Well-Known Men at Corner Stone Laying of King Radiator Company's Factory.

GROUP OF WELL-KNOWN MEN.

The corner-stone laying of the King Radiator Co.'s factory a fortnight ago brought together a number of well known supply men, as will be seen in the accompanying illustration. The "twins," "Bob" Cluff and "Fred" Somerville, will be recognized in the front of the group on the left side. The second to the left is Architect F. H. Herbert, and the third, M. J. Quinn, of Cluff Bros. W. J. Cluff is wielding the trowel on the corner of the building. D. McArthur, of the Standard Ideal, is in a characteristic pose, with a cigar against his white vest, and over his left shoulder, Lorne Somerville, of Somervilles, Limited, has tried to disguise himself behind a broad smile. The third from the right side is Dr. McMahon, financially interested in the King Radiator Company, and next him is George Burman, who is to be superintendent of the radiator works.

Tricks of the Trade

Send in your ideas, sketches or jobs you are doing, and anything of interest to your fellow-workmen. Remuneration will be made for such contributions.

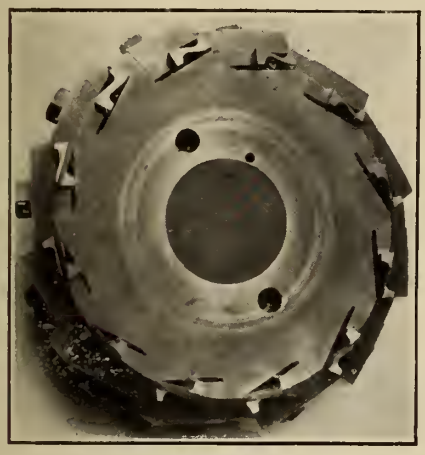
WAYS AND MEANS OF DOING THINGS

AN INSERTED TOOTH FACE MILLING CUTTER.

By Robert P. Keith.

After having placed an order with a prominent milling machine manufacturer in the east, the question next arising was: "What kind of a face mill will we use on this machine?"

The machine in question is of the duplex type; independently driven spindles; independently adjustable, vertically and horizontally, and it is intended that this machine shall drive eight-inch cutters, removing from 1-32-inch to ⅛-inch from the surfaces of gray iron castings; the width of these castings presented to the cutters being approximately 7⅜-inch maximum, to 3½-inch minimum.



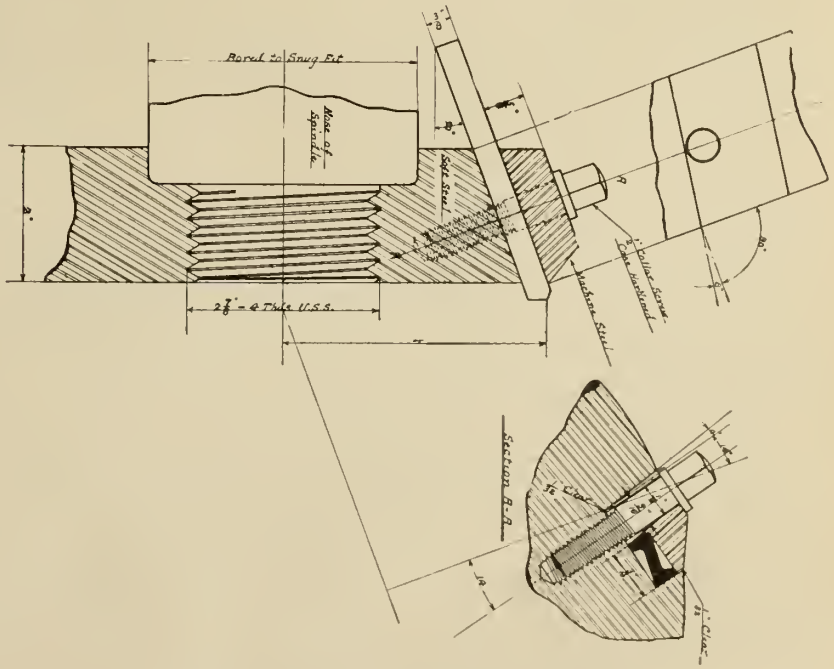
Inserted Tooth Milling Cutter.

After considering the matter it was decided that it would pay us to design a special miller for our purposes. Thus we went ahead, backed by the courage of our own convictions in the matter, and designed a pair of mills as shown in the accompanying illustrations.

The soft steel forgings or blanks were secured for each of the bodies and turned up, bored and threaded to fit the right and left spindles on the machine. Chunks of cast iron were then gripped in the lathe chuck, bored and threaded to fit snugly on the ends of the spindle of the lathe, on which they were then mounted. The rough ends of these chunks were then turned and threaded to fit the threads already in the cutter blanks, which were then finished all over, running on this cast iron adapter. This procedure was followed out with both mills, the making of the cast iron adapter—as it might be called—being necessary in order to mount the blank on its own centre for the outside turning.

Pieces of steel were then turned up, threaded on one end to fit the blanks and turned down to the proper size, and tapered on opposite end to fit the hollow taper arbor of our milling machine indexing centre. Holes were drilled and tapped out in the small taper ends of these pieces of steel, so that we might introduce a cap screw from the back end of the milling centre and draw these studs or arbors in the indexing device snugly. This being done, the milling cutter blank was secured on to the threaded nose by a dowel pin after having been screwed on tightly, and the work of milling begun.

The rest of the operations need no especial description, unless it might be, perhaps, the grinding of the cutters, which is accomplished in an ordinary cutting grinder, the cutters being ground tangentially instead or radially as usual. Particular attention is called to the steel used for the cutters, namely, ⅜-inch by ¾-inch patent "Z" bar section Novo, which, it will be seen, requires but little grinding in order to clear the cut.



Working Drawing of Inserted Tooth Face Milling Cutter

Attention is also called to the feature of giving the cutter both top rake (8 degrees) and side rake (14 degrees); most designers being satisfied with the feed and speed without chattering, and, therefore, quickly dulling the teeth, which were 18 in number, against 12 in the mill we made. This cutter would also easily stall the machine, whereas the other mills do not seem to tax the

Not being satisfied that our expenditure in the way of time and labor on these mills had been altogether wise, a standard design of inserted tooth mill with taper pin binder and ¼-inch x 1-inch inserted teeth was tried out on this same machine. This mill would not take over 1-16-inch cut at the same rate of

Not being satisfied that our expenditure in the way of time and labor on these mills had been altogether wise, a standard design of inserted tooth mill with taper pin binder and ¼-inch x 1-inch inserted teeth was tried out on this same machine. This mill would not take over 1-16-inch cut at the same rate of former. After the completion of the work and the mounting of a piece on the mill for the trial cut, the time had evidently arrived for someone to either disappear or else loosen up his clothes to make room for expansion. The mills during the trial cut were running at 25 R.P.M., at a feed of .112 per revolution, which would mean a table feed of 2.57 inches per minute, and a cutting speed of 52.4 feet per minute, the depth of cut being approximately 3-16 inches.

This cut was taken without trembling, chattering or noise, and after having taken several such cuts it was evident that a somewhat slower speed would be better, and, consequently, this was reduced to 23 R.P.M., at which the mills are now running very satisfactorily indeed.

belts seriously with our cutters. The standard cutters shove or scrape off a very fine cut per tooth, whereas our mills turned off a curly chip, as a properly ground lathe tool should do.

Finally, the points worthy of consideration are the manner of wedging in the cutters, as shown in figure 2, the unusual size of the teeth, the unusually small number of teeth, and the extra thickness of blank in which these teeth are held, together with the feature of top and side rake, as well as clearance, which was ground to 5 degrees.

Courtesy is due the liberal policy of the management in executing this work, as well as the interest and co-operation of foreman and toolmakers.

It is now time for the woodmen to appear with their axes.

FIXTURE FOR CUTTING KEYWAYS ON THE SHAPER.

By Gorman Dizer.

The accompanying drawings represent a splining bar and fixture that were designed for holding work, especially for splining milling cutters, but which could be used for other work.

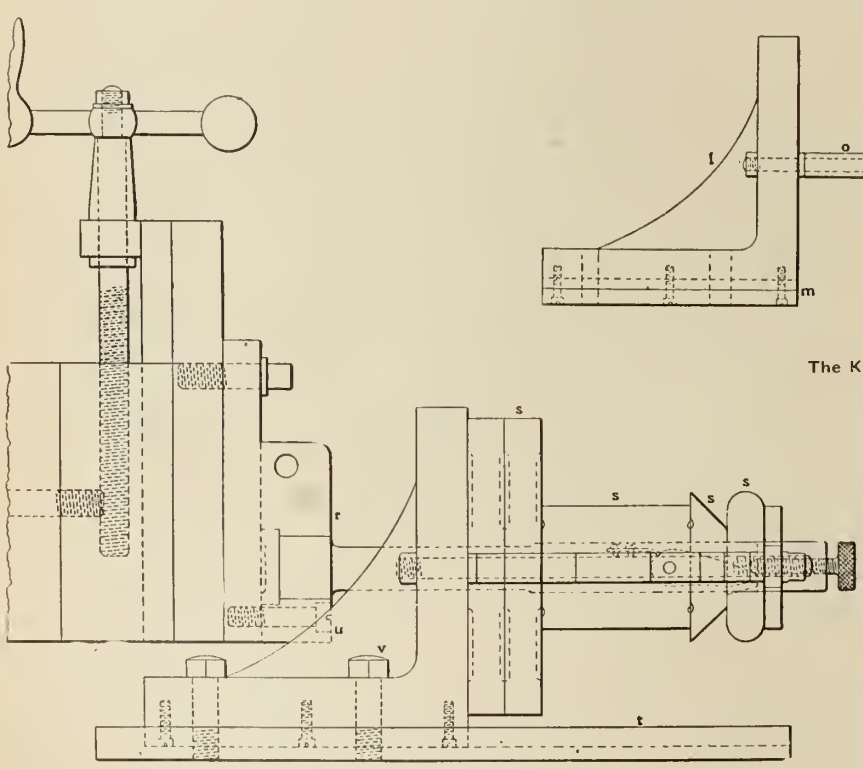

Fig. 7—Fixture in Position on the Shaper.

In the shop where this fixture was made and used it had been the practice to mount the cutter blanks, before milling the teeth, in a chuck or upon a face plate in the lathe and cut the spline with a tool mounted upon the carriage, the carriage being run back and forth by hand. This proved an arm-breaking and cuss-word evoking job, as there were a lot of them constantly coming along to be splined; but the advent of the bar and fixture herein described quite changed the aspect of the universe to the man on the job, inasmuch as splining cutters became almost a pleasure, and incidentally a few dollars were put in the bosses' pocket.

Fig. 1 shows a side view of the bar complete, fig. 2 a top view, fig. 4 an end view, and fig. 3 a side and end view of the cutter.

The bar was made of tool steel pack-hardened and ground at (d), fig. 1, to a working fit in the holes in the cutter blanks, which were reamed 0.006 inch under size to allow for grinding after hardening.

At (c), fig. 1, the bar was turned about 1-32-inch smaller than at (d), to do away with unnecessary friction and trouble in fitting. At (b) the bar was ground to fit the hole in the clapper block of the shaper in which the bar was used, the thickness of the shoulder at (a) being fitted very carefully to the depth of the recess in the clapper block, so that when the bar was put in place and the clapper block bound down by two screws (u), fig. 7, the bar was held securely against any turning or end movement, and at the same time was not forced out of line with the shaper ram.

The cutter (f) was made of tool steel and was left rather hard, as it was well supported against any bending strains by being fitted closely to the slot milled completely through the bar. The hole in the cutter was made a running fit on the pin (i), the pin being a drive fit in the bar. The flat spring (g, fig. 1) was held in place by two screws (h) and pressed against the side of a notch (j) let in the cutter (fig. 3), the pressure of the spring tending to throw the cutter upward, away from the work, and the turning of the knurled screw (e) tending to force it down, the point of the screw bearing against the rounded back of the cutter.

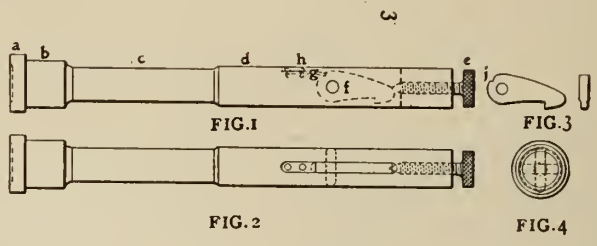

FIG. 1

FIG. 3

FIG. 2

FIG. 4

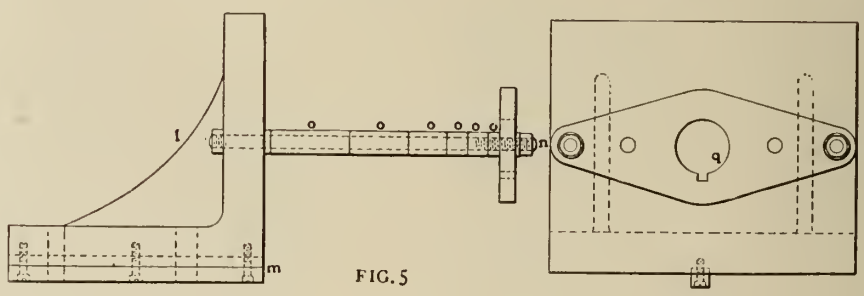

FIG. 5

FIG. 6

The Keyway Cutting Fixture.

The cutter had clearance from the cutting edge upward, and from the cutting edge backward the clearance was very slight, so that the cutter could be sharpened repeatedly by grinding off in front, without changing the size of the spline materially.

The fixture for holding the work, shown in side view fig. 5 and front view fig. 6, consisted of the cast iron angle plate, k, (fig. 5), the long shoulder bolts (n), the collars (o) and the clamp (p). The angle plate had a hole bored through it $\frac{1}{8}$-inch larger than the largest splining bar used. The clamp (p) had a hole of similar size.

In operation, the screw, e, (fig. 1) was turned back until the cutter came up inside the bar. The clapper of the shaper was then raised, the regular tool post removed and the splining bar put in its place. The clapper was then fastened down securely by the two screws, as shown in fig. 7, binding the bar firmly in place.

The knee of the shaper was then brought to such a height and lateral

position that, when the angle plate was put on, the hole in the latter registered approximately concentric with the bar. The angle plate was then put on, the bar passing through the hole in it, and fastened down by three hexagonal-head screws, the key in the bottom of the plate fitting in one of the slots in the shaper bed, locating the plate laterally and at right angles to the bar.

The shaper ram was then brought forward until the entire working length of the bar was in front of the angle plate, the clamp and collars removed, the cutter blanks slipped on the bar and pushed back against the angle plate, the clamp replaced, and the nuts screwed home, binding the cutter blanks firmly against the plate.

The stroke of the shaper was then adjusted so that the cutter came past the end of the blanks on both the forward and back strokes, and the shaper started.

The tool cut on the backward stroke of the shaper ram, the belt being crossed. As the bar came through the front end of the blanks, the screw was given a slight turn to the right, forcing the cutter down to the work; on the return stroke the cutter was pulled through the whole length of all the blanks, the chips flying out back of the angle plate. At each succeeding stroke of the shaper ram, the cutter was set down a little farther, there being ample opportunity for the fingers to grasp the screw, turn it and let go from the time it first protruded through the blanks until it was drawn back by the return stroke of the ram. Oil was occasionally squirted in at the top of the slot in which the tool worked, and, running down around the bar and the edge of the tool, lubricated both the cut and the bar in the blanks.

Fig. 7 shows the bar and the fixture in place on the shaper end and a set of miscellaneous blanks clamped on in readiness to be splined.

The collars shown on the bolts in the face plate were not used when the fixture was worked up to its capacity, but were provided to be put on between the clamp and the nuts when blanks aggregating a shorter length than those shown in the drawing were to be splined.

One lot of blanks could be removed and another lot put in place in a few minutes, as there was no adjusting to do aside from simply stringing the blanks on the bar and fastening with the clamp.

As everything was rigidly braced and there was no possibility of the cutter springing away from the work, a cut as heavy as the shaper belt would pull could be taken at each stroke.

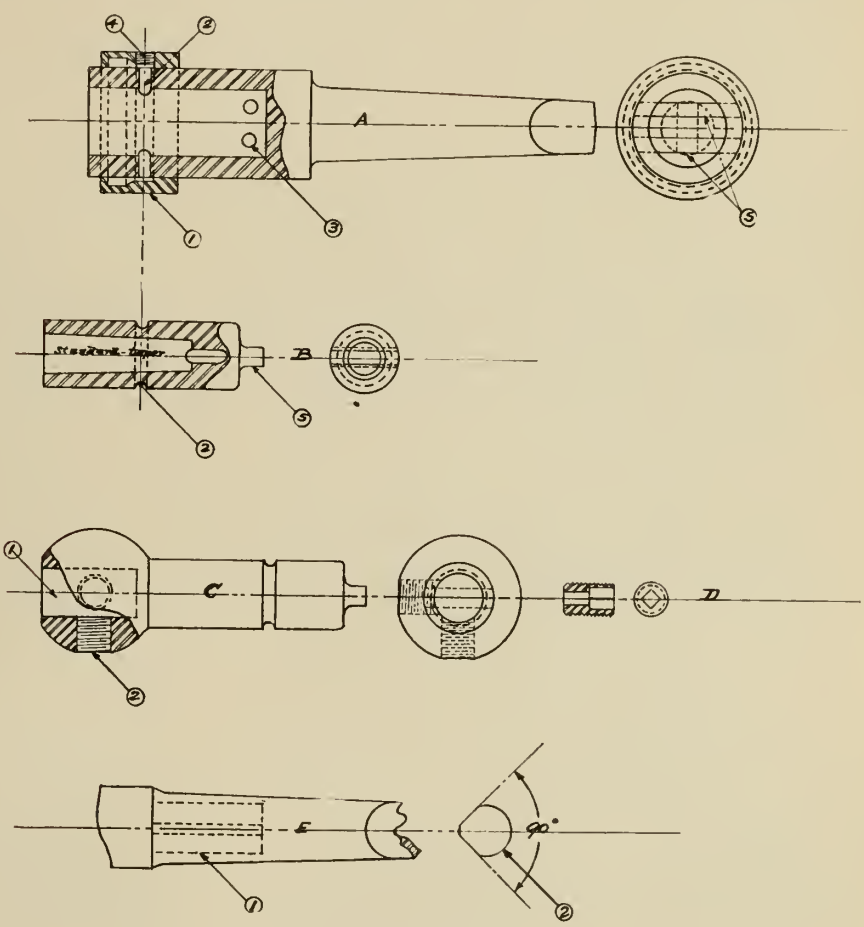
The braces on the angle plate were so spaced that the shaper head could come between them right up to the angle plate, thus doing away with any extra length of bar.

This device worked to perfection. Three sizes of bars were made, for $\frac{7}{8}$-inch, 1-inch and $1\frac{1}{4}$-inch holes, and $\frac{1}{8}$-inch, 5-32-inch and 3-16-inch keyways.—American Machinist.

DRILL PRESS SLIP COLLETS.

By F. E. Lauer.

With the use of the following tools on drill presses where different sizes of drills are being constantly used on repetition work, they will prove themselves a time saver, and at the same time dispense with the abuse drill collets and drills usually get. The holder (a) fits into the spindle of the drill press, and all sizes of drills smaller than the bore of the drill press may be operated in it. We may use three different sizes of standard taper shank drills with this holder by using three collets like cut (b), which are reamed to suit Nos. 1, 2 and 3 standard taper shank drills. A man will have a drill in each all the time, if necessary, and sometimes it is necessary to have two or more collets, with the same number of taper shanks, to do the work he has got. Its usefulness can be readily seen, however, when one is able to just lift the collar which is on the outside of the holder while it is running and the collet and drill will drop out. It will be seen that when the collar 1, fig. (a), is raised it has a greater space for the head of the pin, and when the weight of the collet (b) rests on the pins they slip back, just allowing it to be withdrawn; when another is to be inserted, the rounded corner at the tang end of (b) will push back the pins when the collar is raised and the pins will locate themselves immediately when the collar is dropped. Another feature is the short tang, with its rounded corner, which corresponds with the pins in the holder. Going back to the holder, it will be seen that there is no slot drilled for the tang of the collet, this being dispensed with by hardened steel pins, so it can be readily seen that it is not an expensive tool to make.



Drill Press Slip Collets.

4, fig. (a), is a tapped hole for inserting the two small hardened pins. 5, fig (a), shows the two pins placed, showing the box for the tang to fit in and the dotted lines; in the background is the small end of the shank and tang. The collet (b) is from 005-inch to 010-inch smaller than the bore in the holder, so as to insure freeness.

Fig (c) is the collet for holding reamers and straight shank drills, and the feature of this holder is the binding screws being at right angles to each

other and the use of a large square hole set screw, as fig. (b). These screws are usually about 18 pitch and, being hollow, bind the shank over a much larger area than the ordinary screw and reduces the torsional strain a great deal. Another great difficulty to overcome is the constant breaking of tangs of drills and then never getting attended to properly, and if these drills were turned and milled as the dotted lines in fig. (e) and fig. 2 (e), and used in the collet (c), it will be found that they will outlive the drill with the tang.

A FEW TEST DEFECTS OF INTERNAL COMBUSTION ENGINES.

By H. J. Church.

I propose to outline here a few of the faults which are met somewhat frequently in the testing of gas and gasoline engines. The defects may be roughly divided into two classes: First, those which are due to defective water jackets; second, those connected with the actual running of the engine.

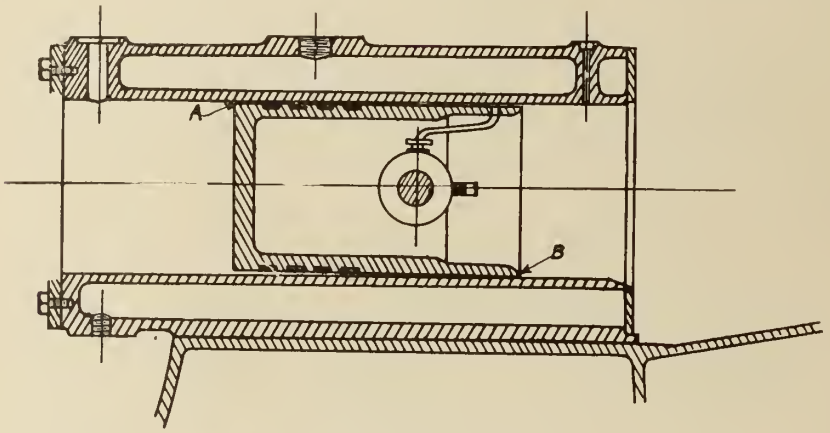


Fig. 1.–Showing Piston Bearing at A and B.

Leaks in Water Jackets.

Under the first heading will come all leaks in cylinder jacket, head and exhaust shell. Those in the cylinder water jacket are usually the result of the presence of porous metal, and if not of an extremely bad type, may be overcome by the careful use of the peaning hammer. Often what at first appears a really bad leak can be entirely stopped. Usually after peaning we give the cylinder a treatment of sal-ammoniac. The sal-ammoniac is dissolved in hot water, in the proportion of one pound sal-ammoniac to five gallons of water. After standing for twenty-four hours or longer (a week is none too much to obtain the full benefit of the treatment) the cylinder is emptied, allowed to dry off, and then is retested. The action of sal-ammoniac on cast iron is too well known to go into detail.

The troubles in the exhaust shells and cylinder heads generally necessitated the scraping of same. One plan was tried with good results with the heads. The leaks here usually occurred in the suction valve port. The heads were stripped and sent away to be galvanized. This completely overcame the trouble. The great disadvantage was the remachining necessary after the treatment.

Troubles in Running Engines.

The piston will usually require more or less attention. Knocking, thumping and blowing are the three troubles that gave us most care. They can be usually overcome by the judicious removal of the high spots, which are observable after the engine has been running some time. Frequently most of the knocking is caused by the back end of the piston expanding more than the front portion, owing to its proximity to the explosive charge. In general, it is safe to allow no bearing at all on the portion of the piston in the rear of the first ring.

One instance of blowing met with was rather interesting. It occurred along the lower portion of the piston. On removing the piston we found the rear end bearing hard on the top of the cylinder, at point (a) in fig. 1, and the front end at the point (b). In reality, the piston was slightly out of parallel with the cylinder. This is shown, greatly exaggerated, in the figure. The removal of the two high spots overcame the trouble.

The pistons should also be examined to find if the dowel pins which hold the piston rings in position are a tight fit. This may be done by filling the piston with gasoline. If there should be the slightest leak the gasoline will usually work its way through.

The crank pin brasses in our vertical engines frequently give us a lot of trouble. Often the presence of grit in the crank case oil is the cause. In a batch of 4 horse-power engines, which we tested, all the crank pin brasses ran hot. We tried all ordinary means to overcome this, but were unsuccessful. At last we removed the cylinder and placed a straight-edge across the top of the crank case, as shown in fig. II. We then measured the distance (a) between the straight-edge and the crank, and also

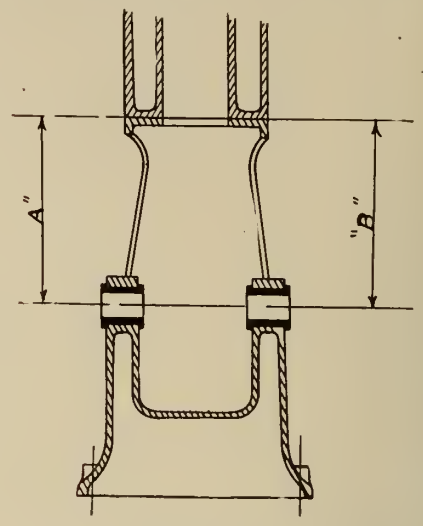

Fig. 2–Showing Bed Out of Alignment.

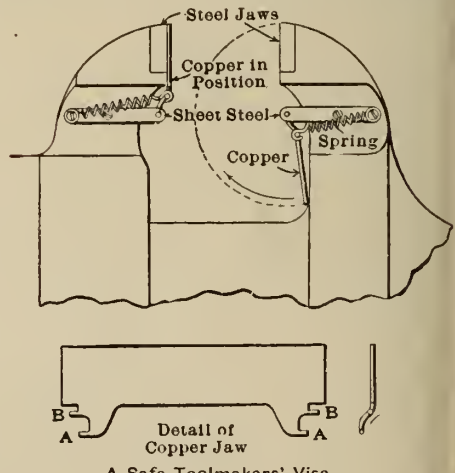
the dimension (b) on the opposite side. There was a difference of 1-16-inch between the two dimensions. The result of this was that the cylinder was tilted slightly out of line. This was sufficient to cause the brasses to run hot, as on squaring up the crank case with the cylinder the brasses ran perfectly cool.

A SAFE TOOLMAKERS' VISE.

By C. W. Putnam.

Everyone who has to clamp finished work in a vise knows the disadvantages of the ordinary jaw caps of copper or lead. They usually fall out at the wrong time and are seldom true enough to clamp a piece of work exactly even.

The strips of sheet steel are screwed to the side of the vise just under the jaws themselves. These carry the lower



A Safe Toolmakers' Vise.

pins or trunnions of the copper jaws (aa), while the springs hook on to (bb).

The sketch shows the left-hand copper face in position and the right face swung down out of the way. It's a good scheme. Try it.—American Machinist.

Developments in Machinery

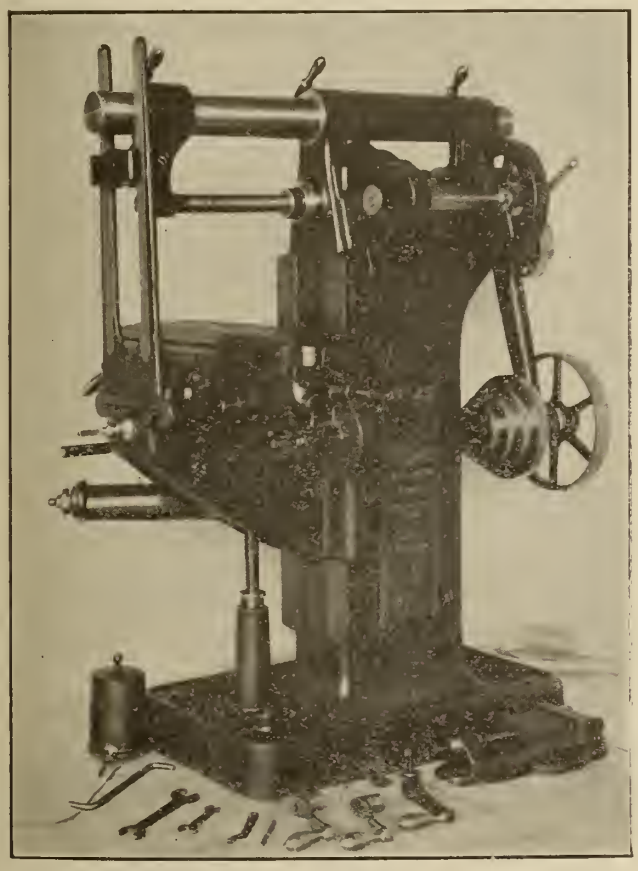
Metal Working Wood Working ***Power and Transmission***

NEW TYPE OF MILLING MACHINE.

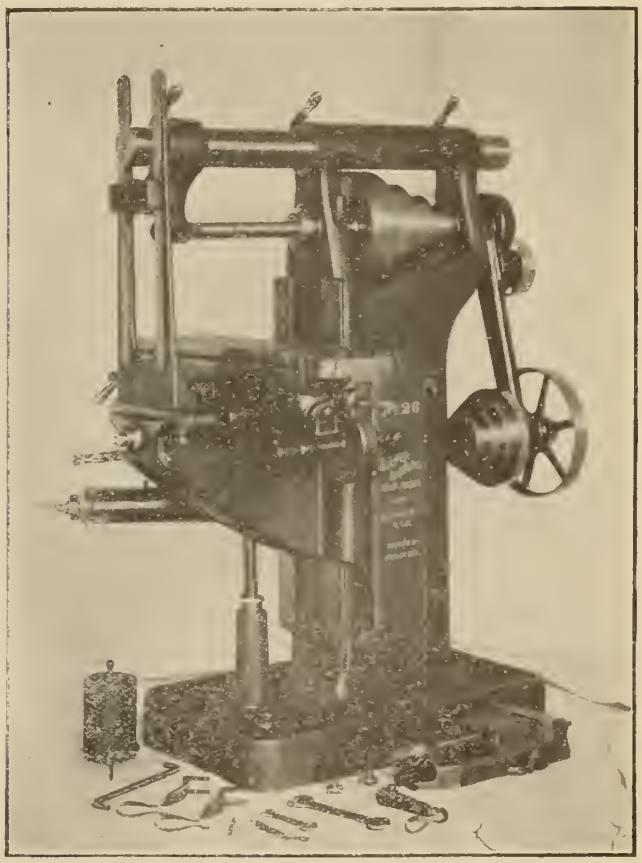
Herewith is illustrated a new Becker-Brainard milling machine, made in two styles, back-geared and not back-geared respectively, known as No. 25 and No. 26. In their design special attention has been paid to the requirements of the manufacturer of small machine parts which are produced in large quantities, such as found in small arms, type-writers, sewing machines and electrical works. In bringing out the new model especial attention has been given to the feed works, that they may be able to withstand the full power of the driving belt, and at the same time give good service in the rough usage to which these machines are subjected. This new feed is driven by belts which get their motion from the spindle of the machine by means of a train of gears, so arranged that the velocity of the belt is sufficient to drive all feeds that the main belt will stand. The changes of the feed are obtained by four-step cones and by interchanging the feed driving pulleys on the back of the machine, giving in combination eight changes, from .007 to .100.

The table is operated by worm and hobbed rack, the worm being driven by means of a worm gear of large size and worm of coarse pitch and of correspondingly high efficiency. The arrangement for disengaging the feed is by a new and novel worm mechanism by which the worm is thrown out of mesh with the gear, and leaves in a path at right angles with the axis of same, overcoming the objection of the old style gravity drop worm of clinging to the gear by friction alone. It also equalizes the wear on the worm gear teeth. The worm is also engaged and thrown out of mesh by the same lever, making in all a neat, convenient and positive method of automatically disengaging the feed and stopping the travel of the table at a predetermined point. The table is also supplied with a hand quick return of 4 to 1 ratio, allowing it to be returned to the original position in the least possible time.

The knee of the new model has been lengthened sufficiently so that a harness brace may be used for the arbor and still have a cross range for the table equal to that of the old style machines. This harness is especially worthy of notice and makes for convenience as well as rapidity. It consists of a brace which is gibbed to the knee slide; a clamp that is fastened to the arbor support yoke in a manner that allows it to be swivelled around its centres, allowing the brace to be removed without removing any bolts. This clamp is made fast to the brace by friction, which gives a more rigid hold than the old style bolt washer and slot arrangement, at the same time allowing of a much stiffer brace. The convenience of this device will be at once appreciated by the operator. The arm, which is a solid steel bar, is adjustable lengthwise.



Becker-Brainard Milling Machine, No. 25.



Becker-Brainard Milling Machine, No. 26.

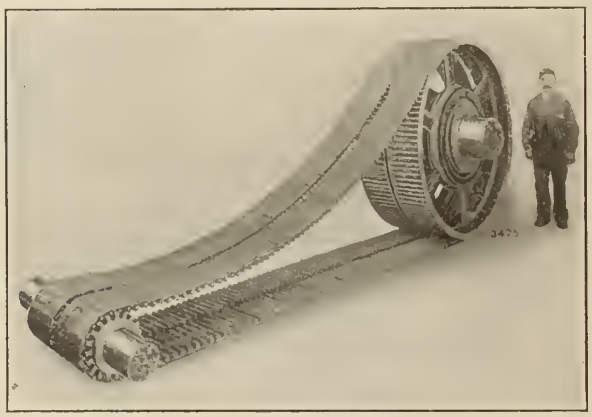
These machines are equipped with a rigid box knee and with a telescopic elevating screw, allowing the machine to be set in any position without regard to beams or floor construction, as the screw does not project below the floor line.

The base of these new model machines has been designed on the same lines as the other Becker-Brainard machines, which are extra heavy, absorbing all vibration.

The spindle cone and back gears are of the standard Becker-Brainard design, the spindle bearing being cylindrical in form, the wear being taken up by concentric compensating bronze boxes.

The appearance of the machine has in no way been neglected, since new patterns were made throughout. Great care was given to the symmetrical appearance of the machines as a whole, all corners being well rounded and the graceful outlines speak for themselves.

The ranges of these machines are as follows: Longitudinal feed, 34 inches; cross feed, 8 inches, and vertical adjustment, 18 inches.



Large Size Renold Silent Chain.

RENOLD SILENT CHAIN DRIVES.

As showing the rapidly increasing appreciation of the many advantages of Renold silent chain drives for high-speed power transmission, we mention two recent applications to different conditions in widely separated parts of the country.

To the Seattle Brewing and Malting Company, Seattle, Wash., belong the distinction of installing the largest Renold silent chain drive in this country—2 325 h.p. parallel transmission to refrigerating machinery; and under the supervision of Wm. M. Piatt, assistant city engineer, Columbia, S.C., a single strand Renold silent chain drive has been put in to operate a Worthington centrifugal pump from a horizontal turbine at a speed of 1,755 feet per minute.

The two chains for the Brewing Company are run side by side on single wheels 14 feet from centre to centre, the load being uniformly distributed by Dodge spring-centres on the driven wheel. The speed is 1,100 feet a minute. The pump drive measures 11 feet 7 inches centre to centre, and has a capacity of 225 h.p.

A Renold silent chain gear, as it is termed by the American manufacturers, the Link-Belt Company, consists of the silent chain and especially cut sprocket wheels. The links, stamped from high-carbon steel, are held together by hardened steel pins and bushings, which make a practically indestructible joint and one which provides the greatest possible bearing surface for a given width of chain.

It is due to the peculiar formation of the links and their method of contact with the wheels that the defects and racket common to the ordinary drive-chain are overcome; the stretch that may result from wear of the teeth is compensated for by the chain automatically assuming a larger pitch diameter while providing the surest possible contact with the driving and driven wheel, one half the circumference of each wheel being always in mesh.

As this continues to be the case, even when the chain becomes worn, it is evident that its maximum efficiency will be maintained although the demand may be severe enough to completely incapacitate ordinary drives.

The chain will run in either direction with uniform, quiet and positive action and is not adversely affected by hot or cold temperature, damp or oily situations.

AUTOMATIC ENGINE STOP.

There is a general impression among engine owners that the governor on the engine is a safety device, and is capable of providing for all emergencies; this is a fallacy, as statistics show that about 200 reciprocating engines and several turbines and synchronous converters have run away in the past twenty months and all had governors.

The governor is designed to keep the speed of an engine constant under variations of load, but as most governors are arranged to operate by centrifugal force they cannot act instantly, as when the load goes off suddenly; it is for this reason that there is real need for a safety device entirely apart from the governor

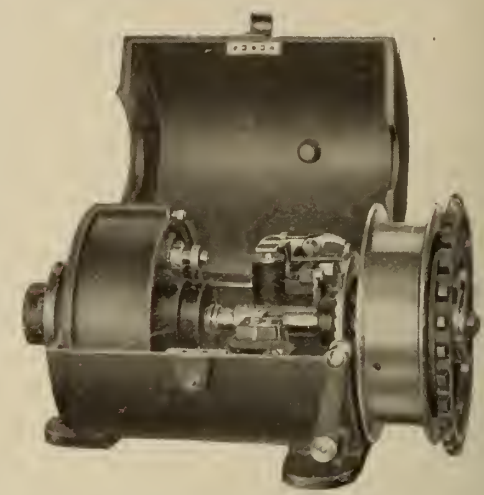


Fig. 1—Automatic Engine Stop.

that will act quickly in case of emergency.

Some of the causes of recent flywheel accidents are: breaking of main belt; loose governor pulley; reversal of dynamo; sticking governor; but chiefly the breaking or slipping of a governor belt and the sudden relief of the load.

While insurance pays the property damages and personal injuries, it does not make good the losses from non-production pending repairs to the plant, nor the wage loss of the employes. Obviously, then, the remedy lies in the providing of such means as will prevent accidents.

There is still another use for the same device; namely to shut down the engine from a distant part of the plant by

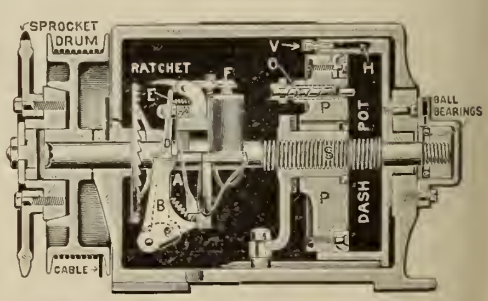

Fig. 2—Automatic Engine Stop.

pressing a switch. One stop is designed to be attached to the governor column, and upon being electrically tripped opens a steam valve allowing steam to enter a small cylinder against a piston, which raises the governor balls to their maximum position, thereby cutting off the supply of steam to the cylinder. In connection with a speed limit device,

this device is known as the Corliss type of Monarch Engine Stop System.

The speed limit consists of a centrifugal device connected to the engine shaft by a chain-drive; it is in circuit with the engine-stop and can be set at any predetermined speed; when this speed is reached, electric contact is made by tripping the engine stop.

Another type of engine-stop operates directly upon the throttle-valve, and can be easily applied to any engine without interfering with its regular work. This is called the Monarch type of the Monarch Engine Stop and Speed Limit System, Fig. 1. It is bolted to the engine frame at any convenient place and is attached to the valve-stem by means of a sprocket wheel and chain. As the valve is opened, a cable, to one end of which is attached a weight, is wound on a drum on the stop and is held by a pawl which engages in a ratchet wheel. When the stop is tripped electrically, the weight is released, revolving the sprocket wheel and thus closing the valve, a dash-pot in the stop forming a cushion to prevent jamming the valve.

In Fig. 2 will be seen a wire cable passing around this drum which is attached to a weight serving as power to operate the stop.

Inside the case and fastened to the shaft is a ratchet wheel engaged by a pawl (B), which prevents the weight from turning the shaft in the direction that closes the valve. This pawl is held in engagement with the ratchet by vertical lever (D), which is held in position by the left end of the armature lever (F). The magnets are placed in circuit with an electric current, and when the circuit is closed, the armature end of the lever (F) is pulled down, releasing the upper end of the vertical lever (D) which also serves as a hammer, striking a lug on the pawl (B) throwing it out of engagement with the ratchet, thus allowing the shaft of the stop to revolve and close the valve by means of sprocket chain attached to the sprocket wheel of the stop, engaging a similar sprocket wheel attached to the throttle valve stem, the weight, as before mentioned, furnishing the power.

At the opposite or right end of the stop is a dash-pot, as illustrated in Fig. 4, which consists of a cylinder into which the piston (P) fits closely. On this end of the shaft is cut a square threaded screw (S), passing through a nut fastened in the centre of the piston (P), so that as the shaft revolves by means of this screw the piston is carried into the cylinder and the air behind its inner face is compressed, forming a perfect cushion. The speed at which the stop acts may be accurately adjusted by turning the by-pass valve (V) that governs the amount of air that is forced through the air passage (H) as the piston moves in. Below this by-pass valve (V) and in piston (P) is located the releasing valve (O); this releasing valve (O), which is opened by contact against the bottom of the dash-pot, is adjustable. After the piston has cushioned and the throttle valve of the engine is near its seat, the compressed air in chamber (H) escapes through this releasing valve (O), allowing the throttle valve to take its seat softly, but yet with sufficient force to close it tightly.

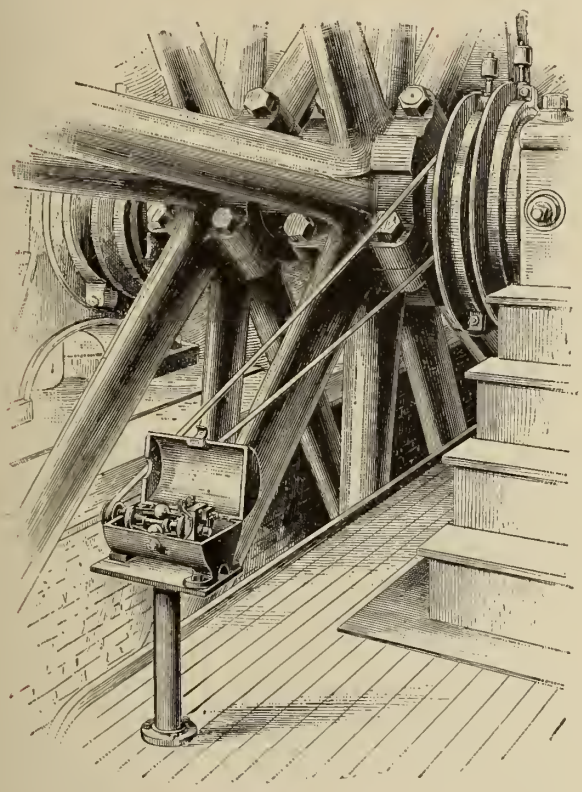

Fig. 3—Application of Monarch Automatic Speed Limit.

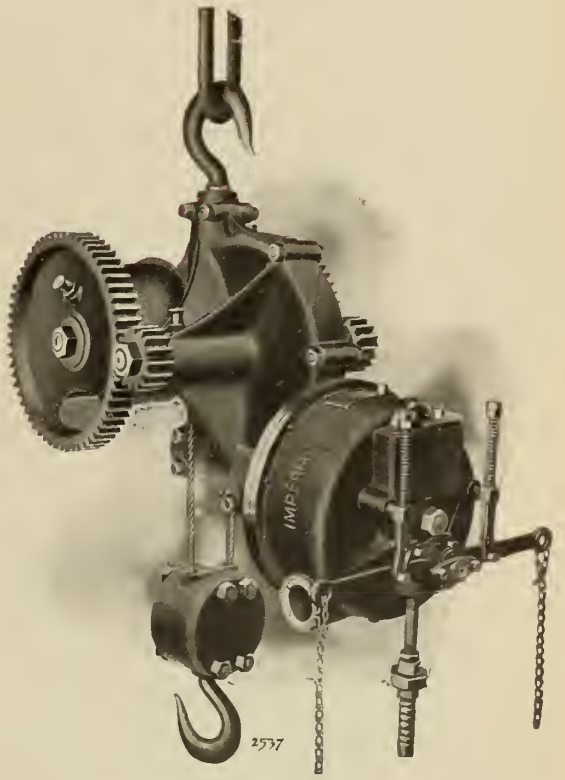
THE "IMPERIAL" MOTOR HOIST.

Accompanying is an illustration of the "Imperial" motor hoist specially designed by the Canadian Rapid Drill Co., Montreal, for use in foundries and machine shops, where the handling of flasks and the erection of machinery requires smoothness of action and accuracy of control. It is simple in design and has small outside dimentions.



Imperial Motor Hoist.

The company's hoist consists of one high pressure, three-cylinder motor, geared to a hoisting drum provided with lifting rope and hook. The controlling valve is positive action and accurately controlled. An exclusive feature is the automatic lock which holds the load in any position without the use of a brake.

Special attention has been paid to producing a machine which will stand the hardest usage at the hands of unskilled operators, with the least amount of care and attention. The motor is fitted with ground steel working parts throughout, and the transmission gear runs in an oil filled case. These hoists are built in capacities from 1,000 to 10,000 pounds.

NEW EBERHARDT GEAR CUTTER.

Accompanying are photos showing No. 2B automatic spur and bevel gear cutting machine, designed and manufactured by Eberhardt Brothers Machine Company, Newark, N.J.

The machine is suitable for such work as lathe and milling machine change gears, feed and adjusting spur and bevel gears, milling of face clutches, cutters and saws, and, in fact, all sylindrical or conical work requiring automatic milling, where either accuracy or rapid production, or both, are essential.

The machine has a capacity of 24-inch diameter, 6-inch face and 8 diametral pitch in steel at a good feed. The construction follows the general design of the line of machines of this company except where the size of the machine allows of different application of the same principles. This is shown in the bevel gear drive to the cutter-spindle, providing a very efficient drive, especially adaptable to the high spindle speeds required by high steel cutters. The changes of speed are obtained by means of gears, immediately driving the bevel pinion.

A segment, graduated in degrees, provides for cutting bevel and mitre gears. The segment is operated by means of a worm, meshing in the teeth in its periphery, thus allowing convenient adjustment. The slide can be raised to 90 degrees, and the machine is very suitable for such work as milling face clutches, etc.

A strap is shown in the front view of the machine, which is used as a brace to give additional stiffness to the slide when raised.

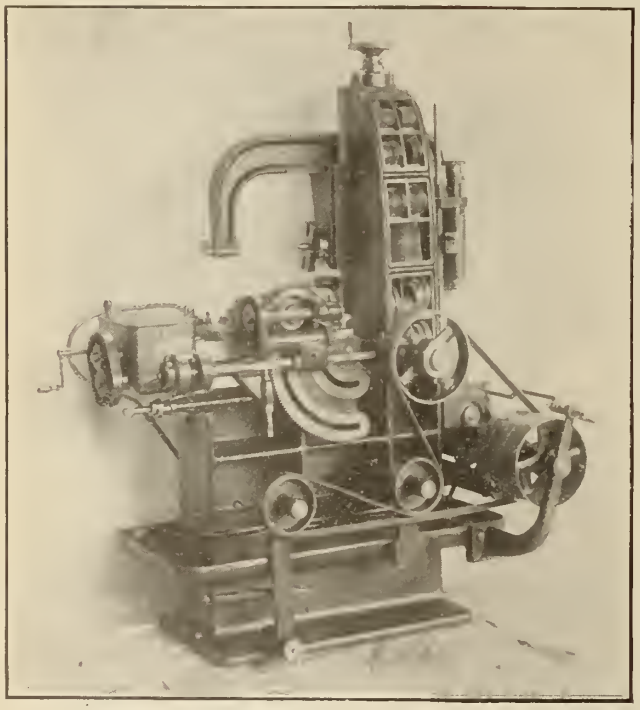
A screw is provided for adjusting the lower slide toward or from the column, to allow for different lengths of hubs. A dial, graduated to thousandths, facilitates this setting. Graduated dials are also provided on the indexing worm, and on the cutter spindle bearing, for rolling and shifting when cutting bevel and mitre gears, and on the depth adjusting screw, for setting the proper depth to be cut.

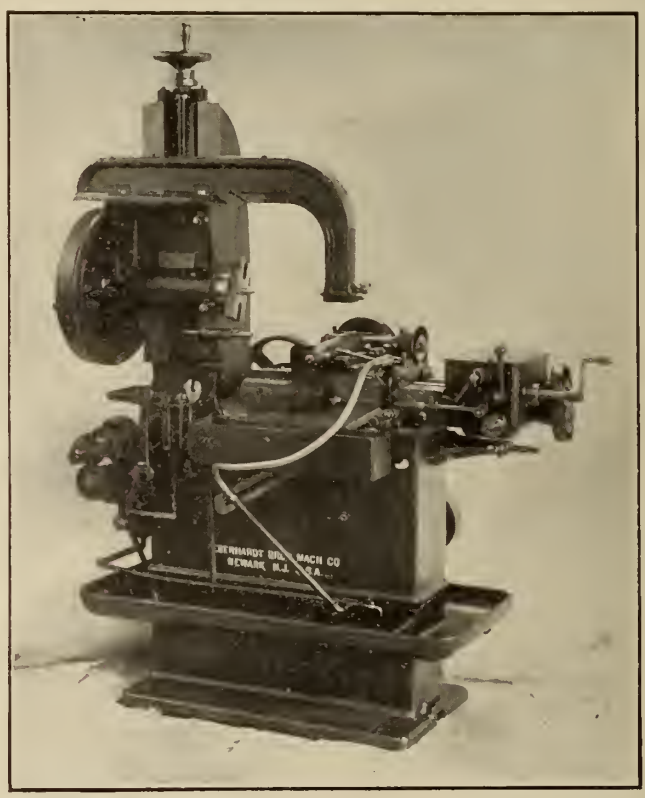
The indexing mechanism is positive, and operates the master wheel, which is large for this size machine, as may be seen.

The outside support to the work arbor is adjustable for different lengths of arbors, but is always centred opposite the work spindle. This is especially convenient in a machine of this class, and allows rapid setting.

The photo shows the work spindle with a 60 deg. centre and dog driver. This is furnished with the machine, and is of use for such work as milling flutes in taps and reamers; for cutting gears on ordinary lathe mandrel; for cutting pinions solid with the shaft, etc. The centre has a taper shank fitting the work spindle hole, and is drawn in and forced out positively, by means of a bolt operated by a handle at the back of the work head. The usual taper and shoulder nut arbors can be used for cutting gears, the hole in the work spindle being No. 10 B. & S. taper. The spindle is of machine steel.

The cutter arbor is solid with the cutter spindle on this size, and takes cutters with 1-inch hole. The chips are caught in the box on the side of the machine, and the oil runs through, being caught in the ample reservoir formed around the frame of the machine. The oil pump affords a constant stream of cutting lubricant, and can be adjusted to regulate the supply.





New Eberhardt Gear Cutter

TRO-THERMIC PROCESS.

The final report of the commission appointed by the Canadian Government in 1903 to investigate the different electro-thermic processes of smelting iron ores and the making of steel in Europe, has been published. As is known, this commission went to Europe, and in 1904 a report of their investigations was issued. The commission was then authorized to conduct experiments on Canadian ores. This was done, and this report is a complete one regarding the experimental work done at Sault Ste. Marie under the supervision of Eugene Haanel, superintendent of mines.

The report contains a detailed statement of the work done and all the measurements made, of the analysis of the pig and slags produced and of the iron ores employed. Plans are given of two commercial electric furnaces which have recently been patented.

Foundry Practice

MODERN IDEAS FOR FOUNDRYMEN

Consideration of Foundry Design*

By F. A. Coleman, Cleveland.

A foundry is a machine composed of a number of parts, each part having a certain duty which should be performed in harmony with the other parts. This machine should be housed in buildings erected to suit the machine.

Raw materials are received or fed into the machine at certain places and the output is finished castings. We think this statement covers the foundry proposition; if it does, we are led to believe there are some peculiar methods employed by many foundrymen.

A foundryman desiring to buy an engine does not go to the engine builder and ask for an engine large enough to fill a building 30 x 40 feet, but he tells him he wants a certain power and type of machine. Nevertheless many foundries start with the size of the building and work backwards to the machine they desire to house. It is this illogical method of building foundries that has tempted the writer to prepare this paper on "Foundry Design," not with the idea of trying to write a treatise on foundry buildings, but of trying to help in the design of the foundry machine.

Many statements made herein will undoubtedly be questioned by foundrymen because they will not line up in all cases with certain exact and known conditions, but general conditions are being discussed and neeessarily general statements must be made; therefore the attempt will be made to treat the subject in a very broad manner.

One expecting to enter the foundry business may have a certain fixed sum of money to invest and desires to produce the best results from this investment; or a certain limited piece of property is to be used and it is necessary to produce the greatest output from the area; or it is desired to produce a certain tonnage of castings. Ordinarily, any one of the above three conditions will explain the beginning of a new foundry, and a careful study will show that in no one of them should the building be allowed to become the determining factor in the design of the machine.

The writer claims that the buildings are drawbacks to the foundry; they keep out light, complicate the ventilation, and are in the way generally.

Problems of Foundry Design.

It seems as if there are but three problems to be solved in designing a foundry, which may be stated as follows :

I. Given a certain sum of money, to produce the largest and most efficient foundry, or

II. Given a certain area of land, to produce the greatest output efficiently at the least expense.

III. Given a certain desired output, to produce the highest efficieney at the least expense.

The general problem is to produce the greatest result with the smallest expense. This of course is what all foundrymen are seeking to do.

There are many kinds of foundries, and while it is not really neeessary in discussing this subject to name them, yet it may be of interest to see how many different lines of foundry work are carried on.

A classification according to metals follows :

1. Iron.
II. Steel.
III. Brass.
IV. Aluminum.

I. Iron foundries produce grey and malleable iron castings.

II. Steel foundries produce acid, basic and crucible steel.

III. Brass foundries produce all kinds of alloy castings, of which we may assume eopper as the base.

IV. Aluminum foundries are almost universally a part of brass foundries and produce alloys containing high percentages of aluminum.

Classifying aecording to methods of melting and avoiding the unusual or experimental methods we have :

I.—IRON—
- Cupola furnaces.
- Air furnaces.

II.—STEEL—
- Open-hearth.
- Converter.
- Crucible.

III.—BRASS—
- Crucible.
- Direct melting.

IV.—ALUMINUM—
- Crucible .
- Direct melting.

Classifying as to fuels we have :

I.—Iron—In the cupola furnace—
- Coke.
- Coal.
- Charcoal.

In the air furnace—
- Coal.
- Gas.

II.—STEEL—In the open-heacth—
- Gas.
- Oil.

Iron melted in the cupola for the converter, with cold blast.

In the crucible furnace—
- Soft coal.
- Oil.
- Gas.

III.—BRASS—In the crucible furnace.—
- Coke.
- Hard coal.
- Soft coal.
- Oil.
- Gas.

In direct melting furnace—
- Oil.
- Gas.

IV.—ALUMINUM—In the crucible furnaee—
- Oil.
- Gas.
- Coke.

Direct melting—
- Coal.
- Oil.
- Gas.

Classifying according to character of work :

I.—IRON—
- Jobbing—light work.
- Jobbing—heavy work.
- Architectural.
- Hardware.
- Stove plate.
- Soil pipe.
- Water and gas pipe.
- Car wheel.

*Paper presented before Philadelphia convention of American Foundrymen's Association.

Pipe fittings.
Machinery.
Electrical.

II.—STEEL—
Jobbing.
Electrical.
Machinery.
Marine.
Railroad.

III.—BRASS—
Jobbing.
Ornamental and art.
Lighting fixtures.
Architectural.
Hardware.
Plumbers' and sanitary supplies.
Steam and hydraulic.
Marine.
Bell.
Automobile.

IV.—ALUMINUM—
Jobbing.
Automobile.

These classifications are not supposed to be complete or exact, but on examining them it will be readily seen that many of these points enter into the foundry design. The foundryman should therefore settle a number of them before considering going ahead with a foundry proposition.

Classification of Work.

The foundryman should determine as closely as possible the class of work he expects to make and the process he expects to use in making it; if the class of work to be made is definitely known, the problem is simplified; too much importance cannot be laid upon this fact because the foundry can then be designed to meet known conditions.

It makes no difference what a foundry may make, all foundries have three general operations which are :

A—Melting
B—Molding
C—Cleaning.

A.—All materials, processes, equipment and labor, necessary to produce molten metal in the molds are included under this head.

B.—All materials, processes, equipment and labor necessary to produce a form of mold for receiving the melted metal come under this head ; as cores are a part of the mold, core making is included.

C.—All materials, processes, equipment and labor necessary to remove adhering molding metal and excess metal not a part of the actual pattern come under this head.

According to this arrangement the melting cost would be the cost of the metal in the mold; the molding cost would be the cost of the molds and cores ready for the metal; the cleaning cost would include the removal of the rough castings from the mold, making it like the actual pattern and delivering to the shipping room; a number of overhead expenses would, of course, be chargeable to these three operations.

Automobile and Marine Engine Cylinders.

We may assume the case of a foundryman who desires to make automobile and marine engine cylinders; he either knows from his experience or finds on investigation that he can produce the best castings with the air furnaces; this of course determines his method of melting.

He next finds that he can depend, or will have to depend, upon the business of certain customers, and that it will be to his advantage to make the work upon some style of molding machine.

If he builds his foundry upon this last assumption, and finds the business comes as he expected, then he will get a certain output; if he has been wrong in his assumption, and he has to resort to bench or floor molding, then his output per molder will be reduced.

The first assumption would require a certain melting capacity per molder, while the last would require a smaller melting capacity per molder.

There are of course many points involved in the ouput of a foundry, but it may be roughly stated that the output divided by the area will be constant for the same line of work.

There are exceptions to this statement, of course. In a brass shop making sanitary work in iron flasks, the molds if poured flat may be stacked three and four high; if poured on end they cannot be stacked and the output of a molder will require a much larger area.

The endeavor is being made to show that many things are peculiar to each metal and to each method, and therefore all these points should be taken up and settled as a part of the preliminary work. It is admitted, that at times no one can determine what should be done, but it is to the foundrymen's interest to reduce the elements of the unknown and the uncertain as much as they can.

Foundry Layout.

It can now be assumed that the foundryman has definitely decided to make a certain line of work in a certain way, and is ready to design a foundry machine which will give him the greatest output of good castings for the least cost.

He should have a map of the property showing streets, alleys, railroads, etc., if the property is or may be affected by buildings adjoining, and these should be noted.

If the area is large and the surface is irregular it may be necessary to make a topographical survey of the tract, but it can be set down as a fact that a careful study of the property itself will show that certain advantages may be gained by designing the foundry with reference to these property conditions.

A building 70 x 100 feet may be designed and do very well on a ten-acre lot, but will be a failure on a lot 70 x 100 feet, surrounded by high buildings in the city.

The amount of metal to be melted to produce the tonnage of finished castings, and the number of molders necessary to handle the metal are next determined.

From this we find the area required for the furnaces, molders, core makers, core ovens and cleaning; the areas and capacities of the storages for metals and fuels are found ; the storage of the flasks, molding and core sands, etc., may be determined; furnaces, molders', core makers', and cleaners' supplies should have a place and require areas which should be determined; pattern and machine shops; pattern storage, locker and wash room; closets and urinals; sand preparation rooms, shipping room, room for holding castings to see if orders are completed ; foundry foreman's office ; main office; power plant and laboratory; it may be necessary to consider all of these.

Certain operations requiring floor space are necessary to every foundry; some of the things noted are needed by some foundries, and all such areas should be determined as closely as possible.

The determination of the various areas required, and such other information as is peculiar to each foundry, places the foundryman in position to start the actual layout of the foundry.

Arrangement of Areas.

The problem now is to make an arrangement of these various areas which will permit of the movement of the materials through the various processes of melting, molding and cleaning, and deliver the finished castings to the shipping room with the smallest amount of labor, the minimum amount of equipment, and the lowest cost.

The storages for all materials received should be close to a central unloading point where they are to be used. The first statement is particularly true of foundries served by sidings.

Fuel and metal should be very accessible to the furnaces. Sands should be convenient to the core room and the molding floors. They may be passed through the sand preparation rooms and then be distributed to the core room and

the various molding floors. Likewise the core ovens should be close to the fuel, and the core room located so as to serve the foundry without unnecessary handling of cores.

Core Departments.

In foundries served by cranes, the ovens should be arranged so that the cores may be handled from the cars by the main bay cranes into place.

This does not mean that the main cranes should be used to load cars, which may be done by core bay cranes. It is not profitable to bake large and small cores in the same oven; the best results are obtained, both in baking and in fuel saving, by baking bench cores in small ovens and floor cores in large ovens. If possible the small core racks should be placed on the division line between the core room and the foundry and accessible to both.

Charging Floors.

In the foundries where the charges are hoisted, the charging floor should be large enough to carry at least one day's supply to avoid shut downs. In heavy shops running two or more cupolas side by side, they should be spaced so that two cranes may serve at the same time; pits should not be located in front of the cupolas.

Provision should be made for the handling of the ladles at the cupolas by small cranes so as not to tie up the main bay cranes.

It is best to pull the heavy and mold cars by haulages independent of the cranes; the heavy cranes should not be called upon to do all kinds of work, which can be better done by lighter and cheaper equipment.

All areas should be regular in form and not cut up, posts on columns should be avoided and should be kept off the molding floors or placed at division lines between bays or floors.

Taking up the form of construction best adapted to foundry purposes, it would seem that of two types, the one which will give the greatest amount of light and the best ventilation should be the one to adopt.

Crane loads and roof loads should be carried directly through columns to the foundations; there is no reason for requiring the actual walls to carry loads.

Light and Ventilation.

Every foundry requires all the light it can get and ideal results are obtained when there is nothing but glass from the sills to the eaves and a continuous line of glass from end to end.

The lanterns or monitors should be wide and high; a narrow monitor is about as expensive as a wide one and not as effective.

The general form of construction as above recommended is so simple and good that it does not seem necessary to mention it, and yet the majority of foundries are much more costly and do not produce as good results.

In addition, whitewash or cold water white paint are worth many times the cost.

If the foundries will wash the windows but once a year they should do it in October and not in the spring; many a foundry can declare a dividend with the money wasted on lighting, when nature stands ready to do it for nothing if only given the chance.

Do not, under any consideration, build any kind of a foundry to do any kind of work with less than 14 feet outside walls. A single bay foundry 50 feet wide should be not less than 16 feet high on the sides.

When floors are to be paved in the foundries, good concrete will give first-class results. The writer is fully aware that the above two statements will be very severely criticized.

Power.

Foundry power is a question which interests many. Shops requiring a small amount of power in the cities can often buy power from the electric companies to good advantage; this is particularly true when there is large fluctuation in the quantity used.

The number of producer gas engines will increase in the foundries as there are many points in their favor; probably the majority of foundries use less than 100 horsepower. The building of successful bituminous coal gas producers in units as small as 125 horsepower, together with the present reliability of gas engines, are strong factors in making this increase.

Lockers and Wash Rooms.

The modern foundries consider locker and wash rooms as necessary; they should be used for washing and dressing rooms only, and should be in charge of some one at the time when the men are going to and leaving work.

The closets and urinals should be located so that it is not necessary for the men to leave their floors; the saving in lost or loafing time is worth the additional cost.

In the larger plants a room for the holding of patterns on their way to the foundry is a convenience. Patterns are thoroughly overhauled to know that they are in condition, with all parts, core boxes, etc., accounted for.

Cleaning Department.

In foundries running a large number of pieces of the same pattern, a casting cleaning room has many points in its favor; castings are turned into this room from the foundry; they are counted and inspected and any shortage must be supplied by the foundry; this avoids congesting the shipping room with incomplete orders. In shops having factories, this room really becomes a store house where requisitions from the factory are filled.

The foundry foreman's office should be located convenient to the foundry to give a good view of the plant; in larger shops requiring a number of sub-foremen, this is not so important.

Distribution of Power.

The distribution of power throughout the plant by motors does away with the necessity of making the location of the power plant a factor in the design of the foundry. The pattern shops, flask makers' shop and machine shop are not an actual part of the foundry, and while it may be necessary to consider them, nevertheless, the foundry layout should not take these into serious consideration.

The actual foundry provides for melting, molding and cleaning; everything else which may be necessary is subsidiary and should give way.

The writer desires, however, to qualify the above statements with reference to foundry plants which are designed to occupy the entire area of the property, and where the greatest output must be secured from this area. Under such conditions everything must be considered as a part of the whole and it becomes somewhat a case of give and take between the various departments.

The east with its older foundries and closely settled localities has been, in many lines of work, forced or led into the construction of foundry plants of two or more stories.

The west is beginning to do the same thing under the same stress of conditions; the melting, molding and generally the core making are carried on on the top floor; cleaning, sorting and shipping and other operations being done on the lower floors; such foundries are generally engaged in light work only.

Building Materials.

Of the materials of construction it may be said that brick is mostly used with wood or steel framing. Fire proof construction is increasing; the foundry, with its furnaces, ovens, hot metal and careless class of employes is peculiarly subject to fires; that this fact is recognized by nearly all foundries is shown by the construction of the fire proof pattern storages.

Oftentimes the destruction of the plant itself during the rush season is fully as serious as the loss of the patterns; this is true of jobbing foundries where customers generally insist upon the delivery of their castings, fire or no fire.

In small or light shops, floors should be planned to give each molder a certain area which can be served very readily with metal either by trolley system or some other method which will take the metal quickly and without confusion to each area.

The great need for designing plants not only for the present but for the future is shown by the large number of foundries, which have a main foundry and a vast litter of dog houses; many foundries are not thoroughly christened until they add such a dog house. But they are expensive; they break up the routine, require extra foremen and generally rob the main foundry of its share of light.

The writer believes that the foundryman should thoroughly study his plans on paper; each problem has an answer which can be more cheaply worked out on paper than on the ground.

It should be remembered that profit is the ultimate end; profit produced by making good castings at a low cost.

The fixed charges should be kept down. Bad design resulting in the expensive handling of materials means useless fixed charges, limited output and of course too high a cost.

Many an expensive investment in equipment or makeshifts could have been avoided in many foundries by the proper designing of the original plant. Many foundrymen now keenly realize that what appeared like a saving in construction has resulted in a heavy cost for operation.

---

*The Malleable Foundry as a Business Venture**

By Dr. Richard Moldenke, Watchung, N.J.

Hardly a week passes but that I receive inquiries regarding the cost of establishing malleable castings plants. The answer I have to write invariably is: "Unless you have at least five tons daily to make—don't."

When one has personally gone through the building of a great establishment, and has the making of hunreds of thousands of tons of malleable castings behind him, caution is the order of the day, and unless the quantity is sufficient and the deliveries from outside unsatisfactory, it is wisest to buy from existing plants rather than to venture upon the little known fields of the heat treatment of white cast iron, for that is what the malleable casting industry comes to in the final analysis.

As a rule the requests for information come from those iron foundries which get orders for plenty of grey iron castings with a sprinkling of malleable, and possibly some steel castings also. The high price they have to pay outside for small lots naturally interferes with their legitimate profit, and hence the desire to produce for themselves. I believe that when the electric furnace is perfected, or made commercially possible, that a different aspect will be given to the case, but at present we have to take things as they are.

The question of embarking into the malleable casting business resolves itself into a market for the work to be produced, and the location to make that work at the lowest cost. It is very rare that a location is picked out unless the territory tributary to it can support a comfortably live malleable plant.

Those concerns which use a large quantity of these castings are the natural pioneers for a given region. The fact that they can make money where they are would be a pretty good guarantee that they can either save money or get their desired deliveries by going into the malleable casting business. Moreover, their profit as manufacturers will carry them over the two or more years of loss in starting the malleable plant.

Advantages and Disadvantages.

To sum up briefly the advantages and disadvantages, I give the following:

(1)—The expanding market for malleable castings, and the great room for improvement in most of the producing works, gives a living chance to the man to go into the business, provided he understands it thoroughly.

(2)—In times of prosperity, plants in existence, where great caution is exercised, must turn away large quantities of offered work, being unable to produce it.

(3)—The moment the malleable castings works are full, deliveries are so desperately bad and slow that attention is turned directly to new enterprises coming in.

(4)—The adaptability of the malleable casting to specialties in railroad, agricultural and hardware lines, is such that the beginner has a good chance to succeed, provided his specialty is good.

(5)—Where absolutely good material is required, it pays the consumer of malleable castings to go into making these himself, provided he has enough tonnage. Only he who knows how easily one can slip up on the quality of the malleable casting, also knows how often this is done, and the customer is not the wiser.

(6)—The malleable product from its adaptability to specialties, and comparatively light castings at that, means a production in quantity of each separate piece. Hence it is not a question of half a dozen castings, but oftentimes several hundred thousand, or in other words, continuous production, with comparatively well regulated and systematized shop cost.

Now the disadvantages follow from the above:

(1)—The expanding market, while making room, also leaves very empty shops in dull times, for the existing plants usually expand with each high wave of prosperity and manage to hold the desirable customers.

(2)—Where the work turned away by the full plants is taken by the beginner, it is at either lower prices, or if at high prices, is lost again when these fall. The ability of the founder who commences, to hold customers who may have been exasperated elsewhere, or his ability to produce cheap enough to cut under, or most likely, his having a specialty which pays the freight, will make or break him.

(3)—The high capital required is a great detriment, being about four times as much as for the same tonnage in grey iron for the works alone. This means more than appears on the surface. The malleable casting process is intricate, the chances of loss great, and it takes fully two years to get a desirable class of men in the shop, after all the bums of the country have passed through it. Hence the chances of no profit, if not worse, for a long time, which must be met and carried until success appears. To give an instance, a rough calculation of the cost of a shop to produce 50 tons of castings daily would come up to say $250,000. By the time that shop would be actually producing the 50 tons daily at a normal shop cost, over double the amount of money will have been expended. Then, however, with a good market, the shop will pay handsomely.

(4)—The high grade of skill required. While the process as we now know it is comparatively simple, we have to reckon with so many factors that an expert in malleable castings is a scarce article. With the range of composition for the iron for various thicknesses of the castings very close, a white iron to start with, with its double contraction, and danger of shrinkage in the interior, with the necessity of chills, the limit to the size and weight, the expansion in the anneal, etc., it is a pretty delicate task to turn out large quantities of various classes of castings, and have them all high grade. Hence the high salaries the important men must be

*Paper presented before Philadelphia convention of American Foundrymen's Association.

paid, and the eternal vigilance required in the works.It must be remembered that your day's work goes into the anneal, and you do not see it for a week. The next day's work the same, and hence a mistake in the temperature of the ovens and you have ruin for possibly a week before you find it out. I remember the slipping off of the night annealer to a nearby speak-easy, with the increase in the natural gas pressure just at that time, which meant thousands of dollars' of damage for two or three hours' inattention.

(5)—The fierce competition that is met with. This is queer but neverthless the case. In spite of all the troubles the malleable casting man has to contend with, he makes himself more by cutting his competitor's prices, until all have very little left. This is primarily the case, because to run a shop successfully and to hold an expensive organization, everybody must be busy. The first aim therefore is tonnage, to keep the shop producing at maximum capacity all the time, practically regardless of prices sometimes. Hard times drop prices in the malleable shop far quicker than in the grey iron establishment. I remember the time when castings were sold to the railroads at a shade less than two cents a pound, delivered. When it is remembered that malleable castings ought to bring a cent a pound more than the corresponding grey iron work, it will be seen what a new man is up against in starting when prosperity is on the wane.

The further reason for this fierce competition is that nearly everybody in this line has a specialty, or several of them, which sell under patents and for as high a price as the community will stand. Hence this velvet can cover a deficit to keep the rest of the works in operation. This, of course, is hard on the man who has no specialty, and hence again, the necessity of having abundant capital until such a specialty is found.

To sum up then, with a good specialty or a number of castings used in the manufacture of well paid for articles, and a sufficient daily tonnage, it is good policy to go into the malleable casting industry as a business venture; but with less than say five tons daily sale, and with insufficient working capital, and men not thoroughly trained in this line, it is better to let it alone.

THE TWENTIETH CENTURY MOLDING MACHINE.

That the pneumatic molding machine is ever forging to the front as one of the indispensable adjuncts of successful foundry practice, and is successfully used to reduce the cost of production in the foundry all will acknowledge, but the cost of installing machines of this kind has deterred the small foundry from doing so.

A very successful machine in use which can be installed at moderate cost is known as the Twentieth Century Molding Machine, patented by J. F. Webb, of Elkhart, Indiana.

The variety of work this machine is capable of handling when placed in the hands of a molder, or handy man, is little understood.

It has often been said: "Some of the best goods come in small parcels."

The Twentieth Century Molding Machine occupies a small amount of space, is moderate in cost, and might be well called the little giant, or giant wonder, as it is a powerful machine in small compass.

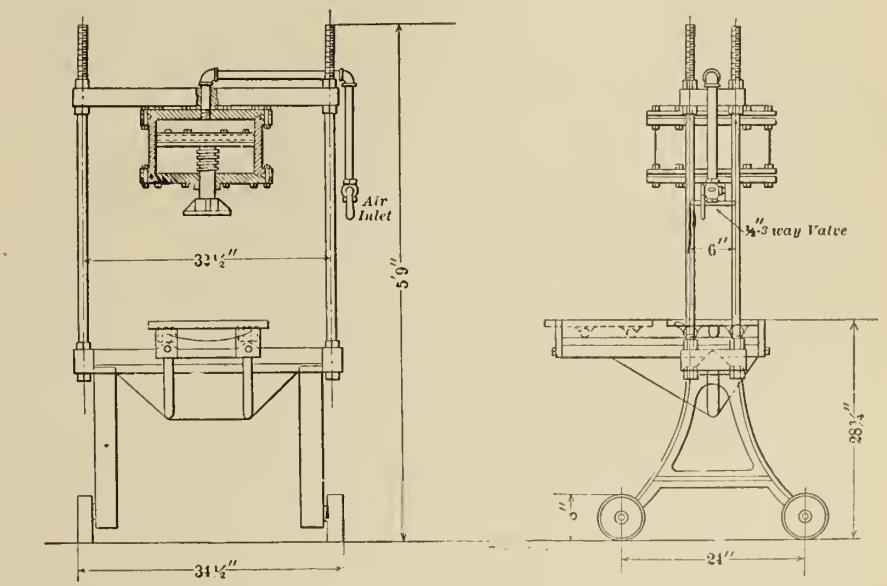
The inventor's ideas shown in the machine are to have a portable pneumatic molding machine in order to obtain the best results.

The machine is portable in order to save the operator the hard labor of carrying the molds the distance he is required to in using a stationary machine, and to have a positive pressure in order to ram every mold the same, and not have one too hard, and the other not hard enough, and another important feature is to have a machine that will not require repairs, as repairs are costly in time and money.

The time the machine stands idle means a curtailment of production, and this in turn means profits lost, and no foreman likes to see the cost of castings mounting upward, and have his employer considering the loss of profits, and customers are apt to become impatient at delays in delivery of castings, when rushed with orders.

The inventor's aim has been to produce a machine simple in construction, moderate in cost, powerful yet compact, one easily understood, and manipulated by molder, or handy man, and easily adjusted to a great variety of patterns, requiring no elaborate equipment, and embodying in every respect the ideas of a practical molder.

When in use the molder pulls the car toward him, places his flask having a plate on which are the pattern between cope and drag on the table, riddles his sand on the pattern, and fills the flask, places the bottom board in position and rolls the flask over, and proceeds with the cope in the same way, then places presser board on top of cope, and by giving the table a slight push, moves it under the cylinder. With his right hand he throws a lever and the air is introduced into the cylinder, and drag and cope are pressed at the same time and piston returns up into the cylinder ready for the next mold. The operator then pulls the flask toward him and starts the vibrator in motion, lifts off his cope, setting it to one side, and lifts the plate having the patterns on it, and the mold is ready for closing.



Twentieth Century Molding Machine.

In order to use a deeper flask the nuts above the upper crosspiece are screwed up to the desired height and crosspiece raised up to them, and nuts underneath screwed up to it, thus raising the pressure head, and allowing a deeper flask to be pressed.

This machine, ready for shipment, weighs only six hundred pounds. Yet a pressure of ten thousand pounds is exerted with an air pressure of 100 lbs. per square inch, and with an ordinary 12 in. x 16 in. flask 40 lbs. is enough.

Selling agents : J. S. McCormick Co., Pittsburgh, Pa.

AMONG THE SOCIETIES

SOCIETY OFFICERS.

Canadian Mining Institute.

President, George R. Smith, Thetford Mines, Quebec; secretary, H. Mortimer Lamb, Victoria, B.C.; treasurer; J. Stevenson Brown, Montreal.

Toronto Branch A. I. E. E.

Chairman, R. G. Black; vice-chairman, K. L. Aitken, secretary, R. T. McKeen.

Marine Engineers.

Grand president, E. J. Henning, Toronto; grand secretary, Neil J. Morrison, St. John, N.B.

Canadian Electrical Association.

President, R. G. Black, Toronto; vice-presidents, R. S. Kelch, Montreal, W. R. Ryerson, Niagara Falls, Ont.; secretary-treasurer, T. S. Young, Confederation Life Building, Toronto.

Canadian Association of Stationary Engineers.

President, Joseph Ironsides, Hamilton; vice-president, Ed. Grandbois, Chatham; secretary, W. L. Outhwaite, Toronto.

Ontario Association of Stationary Engineers.

President, A. M. Wickens, Toronto; vice-president, W. A. Sweet; board of directors, W. Blackgrove, W. A. Sweet, A. M. Wickens and A. E. Edkins; treasurer and registrar to be appointed by board of directors.

Canadian Railway Club.

President, W. D. Robb; secretary, James Powell, chief draughtsman motive power department, G. T. R.; treasurer, S. S. Underwood, chief draughtsman car department, G. T. R.

Engineers' Club of Toronto.

President, C. B. Smith; secretary, Willis Chipman, Rooms 96 King St. W.

Canadian Society of Civil Engineers.

President, W. McLean Walbank; secretary-treasurer, C. H. McLeod. Rooms, 877 Dorchester street, Montreal.

Ontario Land Surveyors.

President, Otto J. Klotz, Ottawa; vice-pres., Thos. Fawcett, Niagara Falls; secy.-treas., Capt. Killaly Gamble, Toronto.

CONVENTION OF AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

The fifty-ninth annual convention of the American Society of Mechanical Engineers was held at Indianapolis on May 28-31. There was a registered attendence of about three hundred.

While somewhat small in point of numbers, the meeting was eminently successful, the papers being of a uniformly high quality and the discussions thereon of unusual interest. A noticeable fact in regard to these discussions was that those who took part in them were men eminently qualified to discuss the subjects under review, and with the result that much information was brought to light.

Large Number of Interesting Papers.

The committee on papers had arranged for a large number of papers on special subjects, chief among which were automobiles and superheated steam. Some of these were prepared by non-members of the society upon invitation of the committee on papers, the authors being experts in their particular lines. Among the papers were: "Collapsing Pressure of Bessemer Steel Lap-welded Steel Tubes," Prof. R. T. Stewart; "The Balancing of Pumping Engines," A. F. Nagles; "The Economy of the Long Kiln," E. C. Soper; "Ball Bearings," Henry Hees; "Air Cooling of Automobile Engines," John Wilkinson; "Materials for Automobiles," Ellwood Hayes; "Special Auto Steel," Thos. J. Fay; "European Motor Cars," B. D. Gray; "Cost of Heating Storehouses," H. O. Lacount; several papers on "Superheated Steam," a synopsis of which appears in this issue of Canadian Machinery.

Report on Machine Screws.

The Committee on Machine Screws made their report.

This committee, which has been in existence for about five years, has been engaged in the work of preparing standard specifications for machine screws. It has presented several reports to the society, but the discussion provoked by each report caused it to be referred back to the committee for further consideration. The revised report recommends a number of changes in the screw gauge outside diameters, enabling the United States standard form of thread to be used without departing from the present pitch diameters, which are large on the small screws and small on the large ones. It was moved and carried that the society accept the report and the committee be discharged.

Visiting Plants.

An afternoon and evening was devoted by the convention to inspection visits to a number of manufacturing plants in Indianapolis, including Attis Engine Works, the Nordyke & Mormon Co., the National Motor Vehicle Co., and the Parry Mfg. Co. Suitable entertainment was provided for the ladies during the convention.

CONVENTION OF RAILWAY MEN.

About 7,000 association members, special guests and exhibitors registered at the forty-first annual convention of Master Car Builders, Master Mechanics, and Railway Manufacturers' Associations at Atlantic City in June. At the same time there was a meeting of the secretaries of the different railway clubs. James R. Powell represented the Canadian Railway Club, Montreal. Subjects of interest were presented and discussed and officers for the ensuing year were elected as follows: Chairman, James R. Powell, Montreal; vice-chairman, F. O. Robinson, Richmond, Va.; secretary-treasurer, Harry D. Vought, New York.

Best Display Ever Made.

The supply men made an exhibit of railway appliances, which for variety and completeness has not been equalled.

Officers of Master Car Builders' Association.

Many things of interest were brought up and discussed by the car builders. Officers were elected as follows:

President, G. N. Dow, mechanical inspector, Lake Shore, Cleveland; first vice-president, R. F. McKenna, M.C.B., Lackawanna, Scranton; treasurer, John Kirby, Adrian, Mich..

Railway Master Mechanics.

The 40th annual convention of the American Railway Mechanics' Association was held at the same time, and was the most successful yet held. Officers were elected as follows:

President, William McIntosh, Central Railroad of New Jersey, Jersey City; first vice-president, H. H. Vaughan, Canadian Pacific, Montreal; treasurer, Angus Sinclair, New York.

CANADIAN RAILWAY CLUB MEETS

At the annual meeting of the Canadian Railway Club the following officers were elected:

President, W. D. Robb, superintendent motive power, G.T.R.; first vice-president, L. R. Johnson, assistant superintendent of motive power, C.P.R.; second vice-president, H. H. Vaughan, assistant to vice-president, C.P.R.; Executive Committee:—W. E. Fowler, T. McHattie, A. A. Mayer, W. M. Dietrich, W. H. Evans, Professor Morgan and G. T. Bell. Audit Committee:—A. G. Walker, W. H. Gault, J. S. N. Dougall, J. Powell, chief draughtsman motive power department, G.T.R., was re-elected secretary, and S. S. Underwood, of the G.T.R. treasurer.

SOME THINGS TO LEARN.

Learn to laugh. A good laugh is better than medicine.

Learn to attend strictly to your own business—a very important point.

Learn how to tell a story. A well-told story is as welcome as a sunbeam in a sickroom.

Learn to stop grumbling. If you cannot see any good in this world keep the bad to yourself.

Learn to keep your own troubles to yourself. The world is too busy to care for your ills and sorrows.

ABOUT CATALOGUES

By mentioning Canadian Machinery to show that you are in the trade, a copy of any of these catalogues will be sent by the firm whose address is given.

WATERWORKS SUPPLIES—An attractive catalogue, a souvenir of the waterworks convention, held in Toronto, enumerating the different articles manufactured by the Jas. Morrison Brass Mfg. Co., Toronto. The catalogue is illustrated, and gives, with prices, a complete list of such articles as are used by waterworks in the laying of services in cities and towns.

HYDRAULIC MACHINE TOOLS.—A large catalogue of hydraulic machine tools, electrical and other special machinery, issued by Henry Berry & Co., Ltd., Croydon Works, Leeds, Eng. This catalogue is an exceptional one in every way. It is very large and very complete, containing 300 pages, 9 by 12 inches; bound cloth. Heavily coated paper is used, so that the fine half-tone illustrations reproduce exceptionally well. The machinery illustrated and described in this catalogue includes hydraulic pumps of different kinds, hydraulic pressure accumulators, hydraulic riveters of very many styles, hydraulic wall, jib and traveling cranes, electric traveling cranes, hydraulic forging presses, hydraulic flanging presses, stamping presses, wheel presses, and many other kinds, hydraulic bending machines, hydraulic packing presses, pipe bending rolls, boiler flue flanging machines, hot-iron saws, hydraulic shearing machines, hydraulic punching machines, hydraulic working valves, and many other specialties.

ROCK DRILLS.—An artistically produced catalogue of "Chicago Giant" rock drills and kindred appliances, is being sent to the trade by the Chicago Pneumatic Tool Company. The book is printed in colors on high grade paper and contains ninety-six pages of matter referring to rock drills. The text is well written and fully explanatory, and is embellished with half-tone engravings illustrating the "Chicago Giant" rock drills and views of parts, followed by several pages devoted to rock drill steels, and an interesting description of the method of lubrication used in the "Chicag o Giant," one of the distinguishing features of the drill. Several pages are devoted to Franklin Air Compressors, another of the company's products, followed by illustrations and descriptions of the "Baby Giant" or one man rock drills, and scenes at work. Catalogue No. 22 is the title of the book.

Copies will be forwarded upon request by addressing the Chicago Pneumatic Tool Company, Fisher Building, Chicago, or 95 Liberty Street, New York, N.Y.

BINDING MACHINE.—We have received from Wm. O. Greenway, manufacturers' agent, 13 St. John street, Montreal, a ten-page circular, printed on fine coated paper, describing and illustrating the "Kennedy" patent binding machine and the work it does. This machine is used by general engineers, electrical engineers, gas fitters, plumbers, etc., for binding all kinds of pipe and iron.

THE 16TH EDITION of Thomas Noakes & Sons' catalogue and price-list of London made steam-fittings for marine, locomotive and stationary engines has just been published, and a copy is received. We have no previous edition to compare this with, but we compliment the publishers on this attractive list, which is conveniently compiled and neatly printed on excellent stock. From cover to cover it runs upward of 123 pages. On application to 4 and 5 Osborn Place, Brick Lane, London, E., England, a copy may be obtained by any subscriber to this paper.

SCREW CLAMPS—A little illustrated booklet, issued by the Jas. L. Taylor Mfg. Co., Bloomfield, N.J. This booklet fully describes, with price lists, the different clamps made by this firm.

PUMPING ENGINES — A handsome catalogue, issued by the Allis-Chalmers-Bullock, Ltd., Montreal, describing with clear illustrations the different types of pumping engines manufactured by this firm. It is gotten up as a souvenir of the American Waterworks convention, held this year in Toronto, and contains Bulletin No. 1,609, which gives, with illustrations, an official report of the tests recently made on three 20,000,000-gallon pumping engines, manufactured by this company, and installed at Bissell's Point pumping station, St. Louis. A complete description of this plant is given, and the book is well bound, and very neat throughout.

STEEL SPECIALTIES—A neat little catalogue, issued by the Cleveland Wire Springs Co., Cleveland, Ohio, illustrating and describing their patented steel specialties.

BOOK REVIEWS.

MODERN AMERICAN LATHE PRACTICE. A practical work on the American lathe, by Oscar E. Perrigo, M.E.; completely illustrated, 424 pages; price $2.50; published by the Norman W. Henley Publishing Co., New York, N.Y.

The author in this volume has treated in a very comprehensive way the history and development of the lathe from its earliest form up to present-day practice; he has briefly discussed its effects upon manufacturing, and has described its practical use for the various classes of work for which it is suitable; and he has also compared from a practical standpoint the different lathes as made by the several American firms at the present day. The contents of the book may be summed up as follows: The American lathe, its origin and development, its design, its various types, including engine lathes, heavy lathes, high speed lathes, turret lathes, and special lathes; the application of the electric motor to the lathe; lathe attachments; lathe work; lathe tools; rapid change gear mechanism; speeds and feeds; power for cutting tools; and lathe testing.

This work will be of exceptional interest to anyone who is deeply interested in lathe practice, as one very seldom sees such a complete treatise on a subject as this is on the lathe. It is a book which is easily read, as it is altogether descriptive, and the numerous illustrations make this descriptive work easy to follow.

AMERICAN PATTERN SHOP PRACTICE.—by H. J. McCaslin. Published by The Frontier Co., Cleveland, O. Sold in Canada by The MacLean Publishing Co. Price, $3.00.

The writer of this book has treated his subject in a somewhat different manner from that adopted by other writers on the subject, the book being for the greater part a record of work with which the author has come into personal contact. The book is divided into six sections, each section dealing with a particular branch of the subject. These sections are: engine patterns; molding and cores; sweep work; gearing; representative patterns; hints; suggestions and rigs.

The chief point of difference in this book compared with others on the same subject is that the molding and core-making as well as the pattern-making has been considered in each case. This makes the discussion very complete.

Special attention has been devoted to the more intricate and important parts of pattern-making, such as core-box work.

LOCOMOTIVES, SIMPLE, COMPOUND AND ELECTRIC.—By H. C. Regan, locomotive engineer; fifth edition, revised and enlarged. John Wiley & Sons, New York. Sold in Canada by The MacLean Publishing Co., Toronto. 932 pages, 8x5½. $3.50.

This is the fifth edition of this well-known work, revised to include the latest developments in steam and electric locomotives. The additional matter in regard to steam locomotives includes a full description of the principle of compounding, including the balanced four-cylinder compound, and the steam superheater. There is a complete discussion of the construction and operation of electric locomotives, including the single phase system, using single phase motors, the polyphase system; using the induction motor; the three phase system, using rotary converters, and direct current motors, and the three-wire direct current system.

The discussion and descriptions throughout the book are practical in character; and practically no theoretical discussions are entered upon. This book is a most complete one on its subject.

IRON AND STEEL MANUFACTURE. The principles and practice of iron and steel manufacture, by Walter Macfarlane; illustrated; 266 pages, 8 x 5 inches; published by Longmans, Green & Co., New York: price, $1.00.

The book is designed to be of value to students in metallurgy, for metallurgists and for engineers. The subject has been treated by considering first the finished material and then the ores, the author's experience showing this to be the best system. Each chapter is self contained. Several chapters have been revised by experts in the subject treated.

The contents of the book include the treatment of the puddling process, crucible steel, tool steel, Bessemer and Siemens processes of steel making, foundry practice, iron and steel castings, malleable castings, case hardening, blast furnace practice from ores and their composition to finished pig iron.

INDUSTRIAL AND TECHNICAL EDUCATION. Report of the Commission on Industrial and Technical Education submitted to the Senate and House of Representatives of Massachusetts; published by Columbia University, Teachers' College, New York.

The volume contains a detailed report of its work in connection with the investigation of the condition of technical and industrial education holding in the State of Massachusetts. Public hearings were held in all the important industrial centres, and much valuable information concerning of all classes of industries was gathered. The question in the report was considered from two standpoints, that of the industries and the adult man on the one hand, and the child on the other.

Importance of Advertising

Engineering advertisements should be written by men well acquainted with Engineering and Mechanics.

Editor, Canadian Machinery and Manufacturing News,
Toronto, Canada.

Dear Sir,—May I, through the valuable columns of your paper, call the attention of those manufacturers, who are interested in engineering industries, to a very important feature of their business, namely, the sales department, which has incorporated with it their publicity department?

When referring to this department, it is perhaps necessary to show from what sources, and in what percentage, the total volume of business originates; and I think it is generally believed that 50 per cent. of the total business originates from personal solicitation; 25 per cent. from advertising, directly and indirectly, and the balance cannot be accounted for, but which is closely allied with the former.

Advertising space being in such constant demand, numbers of publications have sprung up, and the advertisements are simply put there for some reason or another, best known to the manufacturer, without very much attention being paid to the design and the information which the advertisement ought to contain.

As a reader depends a great deal upon the advertising columns for information, it ought to be that this information should be more specific, instead of simply referring to a trade mark or a heavy cut of a particular machine or appliance, and as an engineer's knowledge of a machine depends upon the information he can get concerning it, in many cases, he has to depend upon the arguments of one manufacturer, because he has neither time nor the inclination to delve through large quantities of literature which relate collectively to the subject in question.

Regarding catalogues and literature, there is much room for improvement in this respect, as on account of the great competition that exists, a manufacturer must embody in his literature something more than the superlative term, and as his time is so taken with other features of his business, it remains for him to employ the best talent to explain and illustrate his particular products.

In view of the large expenditure a manufacturer is obliged to make in this direction, he ought to make the most of his space and literature, and these sources of publicity should be part of a complete treatise or work explaining his products.

My experience in many parts of the world leads me to believe, that in many cases, advertising is looked upon as so much of a speculation, which may or may not pay, but no one can tell whether it does or not; so why bother; and catalogues and literature looked upon as the secret of their business.

If, instead of trying to outbid each other for the heaviest type in the advertising columns, a manufacturer would try and show his prospective customers by a lucid explanation, how they could benefit by using his machine or appliance, it would have a tendency to increase his sales.

The time has come when engineering advertising ought to become a special business itself; and it is in no way to be allied with general advertising, except from an artistic point of view, and those people who handle it should be engineers of experience, whose ideas do not run on caricatures, or those things which are not consistent with good business, as it is not possible for a man to explain and illustrate the merits of a farinaceous food one day, and the next, a semi-automatic capstan lathe.

Many large concerns have their own publicity department, which is an excellent thing, but the idea should always be borne in mind, that it is necessary to be a specialist in the business you are thinking of becoming advertising expert for, before you take up advertising; although in many cases, the applicant is an advertising man first, and learns the business afterwards.

As advertising, direct and indirect, is responsible for such a large amount of business, why cannot it be more valuable, and be the means of reducing the expense of personal solicitation?

Respectfully yours,

ALGERNON LEWIN CURTIS,
3706 Spruce St., Philadelphia, Pa., and Chatteris, Eng.

The "ad." is mightier than the cut price.

Industrial Progress

CANADIAN MACHINERY AND MANUFACTURING NEWS would be pleased to receive from any authoritative source industrial news of any sort, the formation or incorporation of companies, establishment or enlargement of mills, factories or foundries, railway or mining news, etc. All such correspondence will be treated as confidential when desired.

Building Operations.

A new armory will be erected at Belleville, to cost $90,000.

A new school will be erected at Port Arthur, Ont., to cost $30,000.

A new school will be erected at Nelson, B.C., at a cost of $60,000.

The Smart Bag Co. will erect a factory on Logan avenue, Toronto.

The General Brass Co., Toronto, will build a factory to cost about $9,000.

The Alberta-Pacific Elevator Co. will build a large elevator at Calgary.

A new reference library, to be erected soon in Toronto, will cost $260,000.

The Massey-Harris Co. will erect a warehouse at Saskatoon, to cost $50,000.

The Canadian Pacific Railway Co. will erect a new depot at Treherne, Man.

The British-American Oil Refineries, Ltd., will establish a refinery in Vancouver.

New car construction works are likely to be erected shortly in Victoria, B.C.

A new steel bridge is to be built over the Pembina river at Snowflake, Man.

Rhodes, Curry & Co. have added a rolling mill to their works at Amherst, N.S.

The G. W. Green Co., Peterboro, have added a large molding shop to their plant.

The lumber mill of W. E. Laking, Cloverdale, B.C., has been destroyed by fire.

The Corby distillery was destroyed by fire during the month, at a loss of $250,000.

A new Roman Catholic church will be erected at Peterboro at once, to cost $40,000.

The Sylvester Bros.' Mfg. Co., Lindsay, Ont., will erect a warehouse at Brandon, Man.

A new Wycliffe College will be erected on Hoskin avenue, Toronto, to cost $280,000.

The saw mill of J. O. Gilbert & Son, Bishop's Crossing, Que., has been destroyed by fire.

A new Roman Catholic Cathedral, to cost $200,000, will be built at Hamilton, Ont.

A one-hundred-barrel flour mill will be erected at Rosthern, Sask., at a cost of $20,000.

Mayor Smith, Regina, Sask., will erect a business block there, at a cost of $40,000.

A new threatre will be erected on St. Catherine street, Montreal, to cost about $68,000.

A bonus has been granted John Hayne & Co. to locate a stair factory at Marmora, Sask.

W. P. Housen, Lethbridge, Alta., will erect a saw-mill on the Belly river, to cost $50,000.

A post office and customs house is being erected at Owen Sound, Ont., at a cost of $75,000.

John Leckie, Toronto, will erect a four-storey warehouse, on Wellington street, in that city.

The Massey-Harris Co. will erect a warehouse in Saskatoon this summer, at a cost of $45,000.

A branch of the Bank of Nova Scotia will be erected at Windsor, N.S., at a cost of $15,000.

The Grand Trunk Railway will erect new freight offices and freight sheds at Brantford, Ont.

The Manitoba Linseed Oil Mills, Ltd., are likely to erect an $80,000 plant at St. Boniface, Man.

H. E. Bond & Co., Toronto, are to erect a five-storey warehouse at Toronto, at a cost of $80,000.

Brown & Co., contractors and builders, St. Marys, intend to erect a box factory in that town.

The ratepayers of Carman, Man., will vote on a by-law to raise $16,000 for a waterworks system.

Messrs. McPherson & Wilband, formerly of Vancouver, are erecting a saw-mill at Abbotsford, B.C.

The wood-working factory of G. S. Eddy, Bathurst, N.S., has been destroyed by fire. Loss about $15,000.

The saw mill of Davis & Kennedy, at Lindsay, has been totally destroyed by fire, at a loss of $15,000.

The Dominion Coal Co.'s output for May totalled 328,917 tons, and the total shipments 279,374 tons.

Substantial enlargements are shortly to be made to the Pere Marquette Railway shops at St. Thomas.

MacGregor & MacIntyre will erect a one-storey iron works on Pearl street, Toronto, to cost $6,000.

The saw-mill of H. C. McCall, Wooler, Ont., has been completely destroyed by fire, with great loss.

J. R. Booth will add a $75,000 sulphide and paper board mill to his big mills at the Chaudiere, Ottawa.

The Construction & Paving Co., Toronto, will erect a two-storey asphalt paving factory, to cost $12,000.

The grist and lumber mills of Jules Patry, near Papineauville, Que., have been completely destroyed by fire.

The warehouse of the Imperial Varnish Co., Toronto, was recently damaged by fire to the extent of $1,000.

Fire lately did damage to the extent of $250,000 to the plant of the Canadian Shipbuilding Co., Fort Erie.

The Merchants Bank of Canada will erect a large building on the present site of the Palace hotel, Vancouver, B.C.

The Bell Telephone Co. have decided to install an entire new plant in Chatham, and place their wires underground through the city.

The Canadian Locomotive Co., Kingston, will spend $300,000 on extensions to their plant during the coming year.

Tenders have been asked for the erection of five steel bridges in district "B" of the Transcontinental Railway.

Fire recently destroyed the grist and saw mill owned by Fred. C. Barrett, near Strathroy. Loss, $8,000.

John Inglis & Co. will build a one-storey galvanized iron blacksmith shop on Strachan avenue, Toronto.

Fire broke out in the elevator shaft of the Smith Table Co. plant, at Mohawk, N.Y., causing $100,000 damage.

Damage by fire to the extent of $1,750 was done to the furniture factory of A. M. Souter & Co. Hamilton.

The wood-working factory of Wm. Gardhouse, Carman, Man., was recently destroyed by fire. Loss about $4,000.

A new paper mill has been added to the plant of the pulp mills which have been operating at Milton Falls, N.S.

The Dominion Transport Co., Toronto, will erect a double-decker steel and concrete stable, to cost about $40,000.

The American Steel Mine Co., Cleveland, Ohio, will erect a factory near Lethbridge, Alta., at a cost of $2,000,000.

A large factory and molding shop, for the manufacture of furnaces, will be erected soon by R. Birley, at Toronto.

Plans have been prepared for new city hall and market buildings to be erected at Brantford, to cost about $70,000.

Fort William will vote on by-laws to raise $94,000 for the extension of telephone, electric light and water systems.

The woodworking factory at Bathurst, N.B., owned by Geo. S. Eddy, suffered by fire recently to the extent of $15,000.

The Carriage Mountings Co., Ltd., Toronto, has commenced operations on new factory buildings at Niagara Falls, Ont.

A new shingle and lumber mill is to be erected soon by J. W. Davis & Son, on the Feaser river, near New Westminster.

The congregation of the Mill Street Presbyterian church, Port Hope, will erect a new edifice, to cost about $6,500.

The Board of Education, Sydney, C.B., are about to erect a new high school building at that place, to cost $40,000.

A new business block, three storeys high, will be erected by the Toronto Savings and Loan Co., in the city of Peterboro.

The factory of the Malone-Manning Wood Fibre Co., Owen Sound, which was recently destroyed by fire, will be rebuilt.

The sash and door factory of the Tobin Mfg. Co., of Bromptonville, Que., suffered loss by fire recently to the extent of $65,000.

Tenders will shortly be called for the erection of a five-storey addition, 140x83 feet, to the Agricultural College, Winnipeg, Man.

The Maritime Mfg. Co., clothing manufacturers, Pugwash, N.S., will erect a three-storey brick factory, 75x40 feet, at that place.

The Belleville Hardware Company's box manufacturing plant, at Belleville, was this month damaged by fire to the extent of $12,000.

A plant, for the manufacture of cement brick has been established in New Westminster, by W. R. Gordon, and is now in operation.

Grey & Hedley, Guelph, and the Stanley Smelting Works are to erect smelting plants shortly on Cataraqui Bay, near Kingston.

The Toronto Engraving Co. are to erect a five-storey office building, at the corner of Adelaide and Duncan streets, to cost $30,000.

A branch factory of the American Machinery and Export Co., saw-mill machinery manufacturers, will likely be erected at Windsor, Ont.

The Minerva Mfg. Co., Ltd., Toronto, are erecting a five-storey mill construction building, 150x60 feet, on Bathurst street, in that city.

The Golden West Soap Co. have purchased a site in Burrard Inlet, Vancouver, B.C., upon which to erect a factory, at a cost of $150,000.

The Colonial Investment and Loan Co., having purchased a site on King street, east, Toronto, will erect a 12-storey office building there.

The J. I. Case Mfg. Co., of Racine, Wis., are reported to have issued bonds to erect factories in Fort William, Ont., and St. Petersburg, Russia.

It is the intention of the Provincial Government to proceed immediately with the construction of a telephone system in the city of Brandon.

Two new fire halls will be erected at Edmonton, Alta., at a cost of $41,000. Each hall is to have a chemical engine and hose wagon and ladders.

The town of Parry Sound is submitting a by-law to the people to grant a bonus of $100,000 for the establishing of a smelter at Parry Sound.

The Sarnia Board of Trade are considering a proposition from United States capitalists to establish a large pipe and tube industry at at place.

The St. Charles Condensing Co., Ingersoll, propose establishing a branch of their business at Tillsonburg, if satisfactory conditions can be secured.

A syndicate of Canadian and United States capitalists are reported to have decided on establishing a steel plant at Walkerville, to employ 500 hands.

D. G. Loomis & Sons, contractors, Montreal, will establish a large brick-making plant at Cote St. Paul, Montreal, on property just purchased for $76,168.

The Brunette Saw Mills Company's offices at Sapperton, New Westminster, together with the store and post office, were recently destroyed by fire, at loss of $500,000.

The Niagara Falls Machine and Foundry Co., Niagara Falls, Ont., are contemplating building new premises, and making additions to their plant and equipment.

Somerville, Ltd., manufacturers of plumbers' and steamfitters' supplies, are about to erect a new brass foundry at Toronto, to cost in the neighborhood of $200,000.

The International Heating & Lighting Co., Cleveland, Ohio, have secured a site at Portage la Prairie, Man., and will commence the erection of a gas plant there.

The Walkerville Land and Building Co., Walkerville, have let the contract to V. Williamson for the erection of three brick blocks, composed of four houses each.

The city council of Sarnia, Ont., has ratified, provisionally, a by-law to advance $10,000 and a free site to the Standard Chain Works, of Pittsburg, to locate there.

The entire plant, together with the finished stock, of the Canada Woodenware Company, Ltd., Hampton, N.B., has been recently destroyed by fire. Loss, $40,000.

The Temiskaming Railway Commission have awarded to O'Boyle Bros. Construction Company the contract for the railway stores building to be erected at North Bay.

The Clark Foundry Company will build new

foundry works at Sydney, C.B. The building will be of steel and concrete, and will be equipped with the most modern machinery.

The Victoria Gas Co., Victoria, B.C., intend making considerable extensions to their plant this season. The company now has 20 miles of mains, and 5 more are to be added.

The contract for the construction of the entire plant of the National Rolling Mills Co., Sydney, C.B., has been awarded E. A. Walberg. The expenditure will exceed $500,000.

Williams & Wilson, Montreal, are building a large addition to the premises on St. James street, Montreal. The new building will be 53x100 feet, four storeys and basement.

The Nova Scotia Steel and Coal Co. are erecting a new forge building, 240x75 feet, which will be fitted with the best machinery necessary for the production of 200 axles per day.

The Clark Foundry Co. will build a new foundry works at Sydney, C.B. The building, which will be of steel and concrete, will be equipped with the most modern machinery.

The International Heating and Lighting Co., Cleveland, O., will start, at once, on the installation of their plant in Portage la Prairie. They will spend some $10,000 on this plant.

Application is now being made by A. M. Fraser for approval of plans fos a 14-storey structure, to be erected on Main street, Winnipeg. The building will be 170 feet in height.

Wilson & Co., of Petrolea, oil experts, have leased about 1,000 acres of land in Caradoc township, about eight miles from Strathroy, and already have an outfit at work near Longwood.

The Cranbrook Electric Light Co. has been organized, and will build a dam and power house on the St. Mary's river, for the purpose of supplying the town with electric light and power.

Work will be commenced immediately on the erection of the brass and iron foundry works of Shaw & Mason, Ltd., at Sydney, C.B. The contract price is said to be in the vicinity of $10,000.

The Cutknife Trading & Realty Co., North Battleford, Sask., will erect a sand-lime brick plant at a cost of $35,000. Besides sand-lime brick, the plant will turn out artificial Indiana sandstone.

The excavation for the new Frontenac gas works at St. Malo, Que., has commenced and the work is being rapidly pushed to completion. Mr. Emmerson McMillan is president of the new company.

Lacombe, on the Calgary and Edmonton line of the C.P.R., has a building boom on its hands. Over $200,000 worth will be undertaken this year. A number of fine business blocks are now going up.

A large furniture factory, for the manufacture of case goods, is being built in Peterboro, and expect to begin operations at once. The directors are, T. W. Oke and E. J. Holcomb. The capital is $10,000.

The Peter Hamilton Mfg. Co., of Peterboro, have suffered a loss by fire to the extent of $10,000. The paint shop and upper storeroom were completely destroyed. It is the intention to rebuild immediately.

Chatham citizens have subscribed the necessary amount for the building of the lake extension of the Chatham, Wallaceburg and Lake Erie Electric Railway. The road is controlled by American capitalists.

The Colonial Weaving Co., Peterboro, propose making substantial enlargements to their plant. The city council has agreed to give them a site adjacent to railway siding, subject to a vote of the people.

On the recommendation of the Minister of Education, the Government has decided to grant $5,000 towards the establishment of a technical school at Sault Ste. Marie, Ont. The new building will cost about $20,000.

J. H. G. Russell, architect, Winnipeg, is asking tenders for an addition to the warehouse of the G. F. Stephens Co., in that city. The addition will be of brick, with stone foundations, and four storeys high.

The new plant of the Canada Nut Co., Toronto, which is being built on the Toronto, Niagara and St. Catharines Railway, just out of Niagara Falls, Ont., is well under way. It is being built entirely of concrete.

The new plant of the Rapid Tool Co., Ltd., Peterboro, is completed, and has been in operation a month. The building is equipped with the latest machinery for the manufacture of augers and all wood-working tools.

The C.P.R. will shortly make large additions to their shops at Winnipeg. The new buildings will cost 100,000, and will include a power house, car shops, planing mill, new tender shops pattern shops and a foundry.

The plant of the Canadian Ramapo Iron Works, Niagara Falls, Ont., is now nearing completion. The machinery is now being installed, and they are delayed by the non-appearance of the electrical equipment.

Montreal is to have another theatre, to be opened next fall. The new theatre will be situated at the corner of St. Urbain and St. Catherine streets, and will be a modern fireproof structure, capable of seating 1,200 people.

Permits have been issued by the city architect for the erection of a three-storey building by the Horological Institute, Toronto, to cost $8,500, and for a two-storey brick warehouse, to be built for the Imperial Glass Works, to cost $14,000.

A by-law to grant a loan of $20,000 to the Wolverine Brass Goods Mfg. Co., Grand Rapids, has been carried by the ratepayers of Chatham. This company will establish a large plant there, to be in running order by January, 1908, and to employ 100 men.

The Canadian Distilleries Co. is being formed by the Gooderhams, the Walkers, Weiser, and other large Canadian distilleries, to erect a distillery at Winnipeg. It will be one of the largest in Canada, and will call for the expenditure of $200,000.

The Peterboro Boiler and Radiator Co.'s factory at Hastings, Ont., is fast nearing completion, and by the middle of July operations will be commenced in the manufacturing line. The machinery is now being installed. Head office is at Peterboro.

Werlick Bros. & Co., manufacturers of pianolas, have purchased the old Preston electric power house. Besides remodelling this building, they will put up quite an addition. They are at present in a part of the building occupied by the Crown Furniture Co.

The Red River Valley Brick Corporation may establish a brick works at Vancouver. It is proposed to erect a plant similar to their present one at Grand Forks, N.D., which has an output of $200,000 pressed bricks daily. Suitable clay has been found.

A big plan is on foot for the establishment of pulp and paper mills in Canada. Five million dollars is the capital, backed by Harmsworth and other Englishmen. Property consisting of fifteen hundred square miles in Exploits valley, Newfoundland, has been secured.

The large reinforced concrete building, which the Canadian General Electric Co. are adding to their plant at Peterboro, is about completed. The machinery and traveling cranes are now being installed. Some three or four hundred additional hands will be required when the work is completed.

The International Harvester Co. have decided to make a large extension to their Hamilton works. An entirely new plant will be constructed, hardly as extensive as the present one, but nevertheless complete and on a large scale. Gas and gasoline engines will be manufactured for the Canadian trade.

There is a proposition before the town of Goderich for the development of electrical energy from the Black Hole on River Maitland, and the building of an electrical road from Goderich north to Lucknow and another branch to Amberley. Some time ago the town passed a by-law granting $15,000 for this purpose.

Shaw & Mason, brass founders, have prepared plans for a frame factory to be erected at Sydney, N.S. The floor space will occupy fifteen thousand square feet. Besides the brass foundry there will be an iron foundry and nickel-plating and sheet metal work will be carried on. The machinery will be operated by electricity.

The Stratford Mill Building Co., Stratford, has been awarded the contract for the Medicine Hat Milling Co., for machinery to double their capacity, at a cost of $80,000. The Milling Company is installing a 100-h.p. steam plant and many large machines of the very latest improved type. The first car of machinery is to be shipped not later than the 15th of July. The ratepayers of Medicine Hat voted a loan of $20,000.

Mining Operations.

The Dominion Antimony Co. is about to erect at West Gore a $50,000 mill for the treatment of ore.

The Plum Coulee Milling Co. will erect a large flour mill in Arcola, Sask., to replace the one destroyed by fire last year.

A big discovery of copper has been made on Skincuttle Inlet, in Queen Charlotte Islands, and it is said the discoverers have turned down an offer of $600,000 for the property.

It is thought that the city of Sydney, C.B., will shortly move for the erection of a new building for high school purposes, which will include facilities for a proposed technical school at that place.

The directors of the Superior mine, near Sault Ste. Marie, announce that they will build a short line from their mine, on the Ottawa Central, west of the Soo., to the Algoma Central. The cost will be $75,000.

The iron mines of the west coast of Texada Island, B.C., are to be immediately opened, and within sixty days steady shipments of ore to Irondale smelter will be made. Jas. A. Moore, of Seattle, is furnishing the capital, and work will be started immediately on the construction of a wharf at Gillies' Bay.

Oil of the highest quality has been discovered in the southwestern section of Alberta province. Huge gushers are now flowing from the earth, and J. S. Williams, an oil expert from Summerlands, Cal., who has inspected the district, has stated he believes a huge underground oil lake exists along the eastern slope of the Rocky Mountains.

It is learned on good authority that the big coal concern organized to operate the areas in and around Port Morien, the North Atlantic Collieries, Ltd., has been successfully floated. The leading promoters and directors of this company, which was organized in 1903, are, B. F. Pearson, Halifax; H. M. Whitney, Boston, and G. E. Drummond, Montreal.

Railway Construction.

Edmonton is installing a street railway system.

Large car works will be established at Bridgewater, N.S., by Canadian and New York capitalists.

The Canadian Northern Railway Co. are considering the erection of machine shops at Longue Point, Que.

The G.T.P. Railway are building a steel concrete bridge to span the Saskatchewan river at Saskatoon.

The Michigan Central Railway Co. are building a new subway in St. Thomas, Ont., at a cost of $66,000.

The C.N.R. and G.T.R. officials are about to decide upon final plans and layout for a joint terminal at Winnipeg.

Work on the new tramway from Lac du Bonnet to Point du Bois has commenced. Mr. Wm. Newman is the contractor.

The Cape Breton Electric Co., Sydney C.B., are laying an electric transmission line between Sydney and North Sydney.

The work of building another section of the double track between Fort William and Winnipeg has been commenced by the C.P.R.

The Winnipeg Electric Street Railway will go ahead at once and double-track Portage and William avenues, and also the Belt line.

The city council, Toronto, have decided to erect a crib-work along the lake front opposite the exhibition grounds, at a cost of $45,700.

The Board of Control, Toronto, invite tenders up to July 16th, for the erection of steel railway bridges for the Lansdowne avenue subway.

The Atlantic, Quebec and Western Railway has asked permission to extend its lines from Metapedia to Edmonton, on the St. John river.

It is said the C.P.R. will replace their wooden passenger cars with cars of steel. The Pennsylvania Railway Co. are placing 2,000 such cars on their line.

The Transcontinental Railway Commission is calling for tenders for the construction of eight miles of the line in New Brunswick, running easterly from Chipman.

Considerable additions are being just now made to the rolling stock of the Grand Trunk, in the delivery of some five thousand freight cars of various kinds.

Contracts for the construction of 6,000 steel cars, costing $6,500,000, have been placed by the United States Steel Corporation, with the Pressed Steel Car Co., the Standard Steel Car Co., and the American Car and Foundry Co.

Prompted by a demand for better steel rails that will make railroading safer, officials of the Carnegie Steel Co. will operate open-hearth furnaces exclusively at the Braddock, Pa., plant. Two new open-hearth furnaces are now being erected.

The Grand Trunk Pacific Railway Company will this month begin the construction of the first of its lines in British Columbia. The line on which the work will be started will be a branch that will tap the main line half way between Hazelton and Prince Rupert, and will run southward to Kitamaat, on the coast.

Announcement is made that the deal, with a syndicate of Pittsburg capitalists, for the control of the Brantford Street Railway, the Grand Valley Railway, and the Woodstock & Ingersoll Railway, has gone through. It is expected to reconstruct the present line to Paris and Galt, and also to put on a better service. The total mileage eventually will be 125 miles, and the sum involved is some $3,000,000.

Miscellaneous.

Jean Gauthier, contractor, Montreal, has assigned.

A waterworks system will be installed at Reliance, Alta.

An electric light system will be installed nt Summerlea, Que.

A post office will be erected at Knowlton, Ont., at a cost of $5,000.

Welland, Ont., has decided to spend $70,000 on a new waterworks system.

Calgary endorsed a by-law recently to raise $125,000, to install municipal 'phones.

Vancouver, B.C., will spend about $750,000 on the extension of its waterworks system.

Messrs. McArn and Mowat, Regina, Sask., will erect an office block, at a cost of $30,000.

The saw-mill of E. Jull, Norwich, Ont., was recently destroyed by fire. Loss about $2,000.

The Amherst Foundry Co., Ltd., suffered a loss by fire last month to the extent of $75,000.

The Western Quebec Milling Co. has been registered in Laprairie, to do a general milling business.

The Canadian Pacific Railway Co. will build a line from Hamilton, Ont., to Guelph Junction, Ont.

The premises of the Union Abattoir Co., Montreal, were destroyed by fire recently, at a loss of $100,000.

The Brewing and Malting Co., Lethbridge, Alta., will erect an addition to their plant, to cost $35,000.

Tenders have been asked for the installation of a complete new fire alarm system in the town of Welland.

The Robert Bell Engine & Thresher Co., Seaforth, Ont., will erect a large warehouse at Moose Jaw, Sask.

The Canadian Fairbanks Co. have opened a branch office in Quebec. R. Miquelon has been appointed manager.

A copper mine has been discovered near Woodstock, N.B., about one hundred yards from the St. John river.

Fire did damage to the extent of $2,000 to the Victoria Foundry at Ottawa, and the plant has been closed down.

The new factory of the London Fence Co., Portage la Prairie, Man., has been damaged by fire to the extent of $75,000.

The limber mill of Coultier & Irish, at Carthage, Ont., together with all the machinery, has been destroyed by fire. Loss, $15,000.

The lumber mill of B. Grier & Co., and the tannery of the Bonner Leather Co., Montreal, were destroyed by fire. Loss, $35,000.

A large power house will be erected in connection with the Canadian Pacific Railway hotel at Victoria, B.C., to cost about $40,000.

The city engineer, Windsor, Ont., is calling for tenders for the construction of 115,000 feet of cement walks, to be laid in that city.

The Renfrew Power Co. have increased the capacity of their power plant from 400 h.p. to 1,000 h.p., at an additional cost of $30,000.

The Niagara Falls Machine and Foundry Co., Niagara Falls, Ont., have a large contract on hand from Toronto and Hamilton for hydrants.

The ratepayers of Sherbrooke, Que., are to vote on a by-law to raise $200,000, for the purpose of developing water power at Westbury, Ont.

D. Conroy, Peterboro, Ont., has been awarded the contract for the construction od the new bridge and dam at Buckhorn, Ont., to cost about $56,000.

Tenders for lighting by electricity, the streets of the city of Hamilton, for five or ten years, will be received by the city clerk, up to noon, July 2nd, 1907.

The city of Peterboro is negotiating with the Light and Power Co., of that place, to purchase its extensive business, which also includes the gas works.

The S. W. & A. Railway Co., Windsor, Ont., have decided to build a power house next to the plant of the Canadian Salt Co., and use exhaust steam from the salt works.

The Niagara Engine Works, Ltd., Niagara-on-the Lake, having made an assignment, the plant and property will be offered for sale, subject to a reserve bid, on July 18th, 1907.

Negotiations are being carried on between Windsor, Ont., and the American Machinery & Export Co., regarding the establishment of a Canadian plant in Windsor by that company.

The ratepayers of Campbellford, Ont., have voted favorably on a by-law to loan Messrs. Jas. and Geo. T. Dickson, $15,000, to aid them in establishing a bridge works in that town.

The Hamilton Cataract Light and Power Co. have filed plans with the Ontario Railway Board for a transmission line from Hamilton, passing through Barton and Salt Lake townships.

A syndicate of Amherst and Antigonish men acquired control of timber limits in Newfoundland and Labrador, comprising 150,000 acres. The purchase price was a quarter of a million dollars.

The Supreme Heating Co. have started active operations on their plant at Welland. The main building, 202x70 feet, will be commenced immediately, and the other building will be added later.

The Manitoba Rolling Mills have commenced operations in their Winnipeg plant. The president of the corporation is Mr. L. A. McElroy, also president of the United States Horseshoe Co., Erie, Pa.

The Radcliffe Lumber Company, Duluth, have recently obtained extensive timber limits from the E. &. N. Railway in the Alberni district, B.C. The company will build one of the largest saw-mills on the coast on the Alberni canal.

Coal has recently been discovered in the vicinity of Saskatoon, Sask., and L. G. Colder, of that town, has just purchased the necessary machinery at Minneapolis for the purpose of properly investigatiug as to tbe value of the new find.

The Northern Engineering Works, of Detroit, Mich., have recently furnished the General Electric Co., Schenectady, N.Y., foundry department, with a No. 84 Newten cupola, with stack 74 feet higb. Tbis cupola will have a capacity of 16 tons per hour.

The iron and steel bounties paid by the Dominion Government for the nine months' period to tbe 1st of April totalled $1,299,801, made up as follows: On pig iron $385,231; on steel ingots, $575,259; on puddled iron bars, $313, and on manufactures of steel, $338,998.

The city of Vancouver has just purchased from the Sengrave Co., of Walkerville, Ont., the first automobile fire apparatus to be used in Canada. The outfit consists of two hose wagons and a double 60-gallon cbemical engine, all of which will be in automobile form.

The furnaces of the Dominion Iron and Steel Co., Sydney, C.B., poured last month some 28,128 tons, an increase of 5,125 tons over tbe best previous record. To do tbis 907 tons had to be poured daily, which indicates tbe large and steady demand now made for pig iron.

A great shortage of labor exists at Fernie, B.C., where it has become impossible to obtain men for outside work. Development work in tbe coal properties is being seriously retarded; the mills cannot get men for the busn and the railroads are exceedingly short of laborers.

The Dominion Power and Transmission Company have filed plans with the Ontario Railway and Municipal Board, for a new transmission line from Hamilton to Decew Falls, Ont. It is said the new line will be completed next winter. The line will be used only as an auxilliary, and when anytbing is wrong with the other two lines, it will be called into requisition.

Among the orders received by the Robb Engineering Co., Amherst, for their celebrated engines are: N. & M. Smith, Halifax; Columbia River Lumber Co., Golden, B.C.; Temiskaming and Northern Ontario Railway; Canadian General Electric Co.; Canadian Westinghouse Co., Hamilton; Somerville, Ltd., Toronto; W. P. McNeil & Co., New Glasgow; Canadian Rand Drill Co., Sherbrooke.

Among the orders received by Darling Bros., Ltd., Montreal, for their Webster Feed Water Heater, Purifier and Filter, are: 2,500 horse-power machine for J. R. Booth, Ottawa; 2,500 horse-power machine for Dominion Coal Co., Glace Bay; 2,000 horse-power machine for T. Eaton Co., Toronto. This is tbe fourth order this firm bas received from the Dominion Coal Co., all tbe machines being over 800 horse-power.

In tbe new pipe foundry of the United States Cast Iron Pipe and Foundry Co., Burlington, N.J., four 5-ton special electric Northern jib cranes have been installed, two of them of the column type and two of tbe transfer jib type. These cranes will assist the overhead traveling cranes, and they are of high speed design, especially suited to pipe foundry service. This company also installed a 20-ton electric Northern traveling crane.

The Scottdale plant of the U.S. Cast Iron Pipe and Foundry Co. have recently added four No. 84 Newten patent cupolas to the melting equipment of their pipe foundry. This gives them in all six cupolas of this make. Each cupola has a stack of approximately 57 feet high and an average capacity of about 16 tons per hour, giving approximately 96 tons hourly capacity. These cupolas were furnished by the Northern Engineering Works, Detroit, Mich.

Among the orders received by the Smart-Turner Machine Co., Hamilton, for their standard duplex pumps, are: R. H. Buchanan & Co., Montreal; Canadian Canners, Belle River; Dominion Heating & Ventilating Co., Hespeler; Robb Engineering Works, Amherst; Stoney Lake Navigation Co., Young's Point; Messrs. Donaldson & Wark, Hamilton; Brompton Pulp and Paper Co., East Angus, P.Q.; Canada Tin Plate Co., Morrisburg; Doty Engine Works, Goderich; the Corporation of Hamilton, Ont.; Messrs. West & Peachy, Simcoe.

English Gauge Glasses.

Baxter, Paterson & Co., Montreal, have secured the agency of the "invicta" and "Adamant" gauge glasses, manufactured by the S. C. Bishop Co., St. Helens, England. These glasses are tested to 5,000 pounds hydraulic pressure. The special feature of these glasses is the fused ends, which give them a greater power of endurance under high pressure.

* * *

Krugg & Crosby to Make Motor Boats.

Krugg & Crosby, Hamilton, are now making gasoline motor boats, under the name of the Guarantee Motor Co. They are making a 2½ and 5 horse-power single cylinder, and a 5 and 10 horse-power double cylinder engine. These engines are reversible, and have a special guarantee.

They are also making a specialty of engine cylinder castings.

* * *

Fire at Greey's Foundry.

The plant of Wm. and J. G. Greey, Toronto, was recently damaged by fire to the extent of $10,000, the east section of the machine shop being destroyed. Besides the damage done to the finished stock and to the working machinery, most of which was badly wrecked, considerable loss was entailed by water, which soaked the belting all through the plant. The intention is to rebuild immediately, the loss being covered by insurance.

* * *

Copper Concentrator at the Soo.

Ex-Mayor Frank Parry, of the Michigan Soo.; Geo. Kemp, F. C. Smith, and other capitalists, under the name of the Superior Copper Company, with a capital of $2,000,000, will erect a big concentrating plant, on the Ontario side of the river, at Sault Ste. Marie. The plant, which will have a capacity of 400 tons a day, will be the largest of its kind in Ontario, and is to be followed in the near future by other big industries. The company will also build a railway, five miles long, from Algoma Central to their Superior mine.

Addition to Safe Works.

J. & J. Taylor, safe manufacturers, 145 Front St. E., Toronto, have just completed and are at present moving into an important addition to their already large plant. The new building is a handsome brick and steel structure 242x60 feet, on cement foundations reinforced by extra heavy concrete piers. The new factory addition, which will cost about $50,000, was necessitated by the growing demand for safes, fire-proof vaults, etc., in keeping with the growth and development of the country. It is of first-class factory construction, one storey with gallery, steel trussed roof with sheet metal outside covering. A forty-ton electric traveling crane is being installed so that the heaviest work may be handled with facility. Power will be supplied by three direct current electric motors running three separate lines of shafting, the latter having been installed. For two years past this company have been running their factory night and day to keep up with orders. About 300 men are employed and 50 more will be required.

Companies Incorporated.

The Provincial Construction Co., Montreal; capital, $20,000; purpose, to carry on contracting business. Incorporators: L. Beauchamp, Montreal, and others.

The Louisou Lumber Co., Ltd., Sayabec, Que.; capital, $200,000; purpose, to carry on a lumber business. Directors: A. C. Dutton, Springfield, Mass., and others.

Pacific Coal Mines, Ltd., capital, $6 000 purpose, to carry on a mining, milling and reduction business. Incorporatoes, J. S. Lovell, accountant, Toronto, and others.

J. E. Sauve, Ltd., Montreal; capital, $40,000; purpose, to carry on lumber business. Directors: J. E. Sauve, manufacturer; R. Sauve, machinist, and others, Montreal.

Norton Telephone Mfg. Co., Toronto; capital, $40,000; purpose, to manufacture electrical supplies, telephones, etc. Provisional directors; J. E. Day, J. M. Ferguson, A. W. Bixel, Toronto.

Parker Car Heating Co., London, Ont.; capital, $16,000; purpose, to manufacture car heating devices, etc. Provisional directors: T. Parker, J. M. McEvoy, E. J. Dawson, London, Ont.

Snap Co., Ltd., Montreal; capital, $90,000; purpose, to manufacture soaps, chemicals, etc. Provisional directors: T. J. Clark, A. L. Malone, barrister-at-law, and others, all of Toronto.

A charter has been granted a corporation of American capitalists, with $5,000,000 capital, to manufacture and sell the devices invented by John H. Parsons, for the consumption of smoke.

Ontario Copper Co., Toronto; capital, $3,000,000; purpose, to carry on a mining, milling and reduction business. Provisional directors are: J. M. Ewing, A. G. Ross and W. S. Edwards, Toronto.

Farley Phillips Co., Montreal; capital, $45,000; purpose, to manufacture cut glass and similar ware. Incorporators are, G. Phillips, W. Smith, Estelle Coriveau and E. Gill, all of Montreal.

Anderson Logging Co., Ltd., Aberdeen, B.C.; capital, $50,000; purpose, to do general lumbering business, and to take over as a going concern the firm of Strand & Jennierson, of the same town.

The Vulcan Portland Cement Co., Ltd., Montreal; capital, $2,500,000; purpose, to manufacture Portland cement. Provisional directors: G. W. Macdougall, K.C.; L. Macfarlane, and others, Montreal.

Kingston Harness Works, Kingston; capital, $40,000; purpose, to manufacture and sell harness and other leather goods. Provisional directors: T. W. Suddaby, W. H. Acton and Wm. Bennett, Kingston.

Louison Lumber Co., Sayabec, Que.; capital, $200,000; purpose, to manufacture lumber, timber, pulp, etc. Provisional directors: H. H. Brodie, A. W. Cameron, Montreal; A. C. Dutton, Springfield, Mass.

Ideal Oak Leather Co., Toronto; capital, $50,000; purpose, to carry on the business of tanners and manufacturers of leather. Provisional directors are: Arthur Gate, W. H. Smith and Geo. Kerwin, Toronto.

Newbury Canning & Preserving Co., Newbury, Ont.; capital, $30,000; purpose, to carry on a canning and preserving business. Provisional directors: J. L. Heatherington, P. B. Robertson, and C. Rush, Newbury.

Chesley Furniture Co., Chesley, Ont.; capital, $40,000; purpose, to manufacture furniture, railway fixtures, rugs, carpets, machinery, etc. Provisional directors: W. G. Durst, J. Hauser and W. Krug, Chesley, Ont.

The Kingston Harness Works, Kingston; capital, $40,000; purpose, to manufacture harness, leather goods, etc. Provisional directors are: T. W. Suddaby, C. F. Suddaby, Kingston, Ont., and J. Bedrad, Gananoque, Ont.

MacLean Cream Separator Co., Sarnia; capital, $40,000; purpose, to manufacture cream separators. Directors, R. V. LeSueur, L. A. MacLean, D. W. H. Lucas, E. A. McDonald and J. W. Hamilton, all of Sarnia.

Faircloth Art Glass and Decorating Co., Toronto; capital, $40,000; purpose, to manufacture art and stained glass, wall paper, etc. Provisional directors: R. T. Faircloth, J. M. Faircloth and G. A. Pringle, Toronto.

The North American Mineral and Lumber Co., Montreal; capital, $49,000; purpose, to prospect for minerals, and to erect saw mills, etc., in carrying on lumber trade. Directors: H. P. Adams, H. J. Cassard, Montreal.

Tillbury Town Gas Co., Chatham; capital, $40,000; purpose, to prospect for and develop oil and gas wells. Provisional directors: R. E. Kiser, G. W. Holmes, Chatham; J. A. Tremblay and J. S. Richardson, Tilbury.

Dominion Exploration and Development Co., Toronto; capital, $1,000,000; purpose, to carry on a mining, milling and reduction business. Provisional directors are: R. J. Tough, K. D. Moorhead and R. H. Patterson, Toronto.

Laidlaw Lithographing Co., Hamilton; capital, $100,000; purpose, to carry on the business of printers, lithographers, bookbinders, etc. Provisional directors: R. Laidlaw, C. R. McCullough and J. I. McLaren, Hamilton, Ont.

The Glen Hayes Coal Mining and Development Co., Winnipeg, Man.; capital, $1,000,000; purpose, to deal in coal, oil, coke, and other metals. Incorporators: G. A. Bull, R. S. Armstrong, Winnipeg; S. L. Head, Rapid City, Man.

The River Plate Shipping Co., Ltd., Montreal; capital, $150,000; purpose, to carry on the business of a shipping company. Incorporators: C. A. McCollough, New York; W. A. Tait, Arlington, Mass., and G. I. Dewar, Ottawa.

Canadian Logging Tool Co., Ltd., Sault Ste. Marie; capital, $15,000; purpose, to manufacture lumberman's tools, etc. Incorporators are: David Wolf, Grand Rapids; Wm. Latta, Wm. Davis, E. S. Gough, and others, all of Chicago.

The Lake Superior Iron & Steel Co., Ltd., Sault Ste. Marie; capital, $1,000,000; purpose, to manufacture and deal in iron, steel, nickel and other products. The provisional directors are: C. W. Thompson, H. B. Johnson, E. Perryson, and H. Todhunter.

Glen Hayes Coal Mining and Development Co., Winnipeg; capital, $... purpose, to mine, sell and deal in coal, coke and other metals. Incorporators are, George A. Bull, R. S. Armstrong, H. C. Hamelin, of Winnipeg, and Sampson Leslie Head, of Rapid City.

Cody Manufacturing Co., Sarnia; capital, $50,000; purpose, to deal in and manufacture all articles of iron, brass, copper, and other metals, and to do a machine shop and foundry business. Provisional directors: A. S. Cody, R. D. Cody and Thos. French, Sarnia.

Portage la Prairie Construction Co., Ltd., Portage la Prairie; capital, ...00; purpose, to manufacture builders' and contractors' supplies and carry on the business of builders and contractors. Provisional directors, Henry Stephens, Wm. Armstrong, Wm. Richardson and Hugh Armstrong, all of Portage la Prairie.

Manufacturers and Manufacturers' Agents

It will pay you to watch our condensed column each month. There are many money-making propositions brought to your attention here. You may find just what you are looking for.

RATES

One insertion—25c. for 20 words; 1c. a word for each additional word.

Yearly rate—$2.50 for twenty words or less, 10c. a word for each additional word.

The above does not apply to notices under the head of "Machinery Wanted." These notices are inserted free for subscribers.

BUSINESS CHANCES.

A GOOD cash paying electric wiring business; a small capital only required; selling out owing to ill health. For particulars apply to Box 31, CANADIAN MACHINERY, Toronto. [8]

MACHINISTS—$5,000 buys at par stock in established manufacturing company, western city; salesmen, machinists, blacksmiths, accountants; here's a chance; assets exceed two hundred thousand and company solid financially; write us if interested. Locators, Winnipeg.

FOR SALE.

BELTING, RUBBER, CANVAS AND LEATHER, Hose, Packing, Blacksmith's and Mill Supplies at lowest prices. N. Smith, 138 York Street, Toronto. (2tf)

CORBETT FOUNDRY & MACHINE CO., Owen Sound, make stacks, tanks, hoppers, etc.; write for prices.

GREY IRON CASTINGS.

WE make all kinds of grey iron castings; give us a trial. Rogers Manufacturing Co., Goderich, Ont.

CASTINGS, machine work of all kinds, the pattern-making undertaken under the supervision of skilled engineers; works outside city; country prices; special terms to the trade. G. P. Wallington & Co., 11 Front Street east, Toronto.

MANUFACTURERS' AGENTS WANTED.

SHEFFIELD manufacturers of tool steel, spring steel, section bars, etc., as advertised on page 22, wish to correspond with reliable Canadian firms with view to sole agencies in certain territories. Address "Newhall," care CANADIAN MACHINERY, 88 Fleet Street, London, Eng.

SITUATION VACANT.

WANTED—Young man well experienced in machinery supply business able to sell and knowing thoroughly all requirements of the trade. Salary, commission and share of profits. Apply Box 32, CANADIAN MACHINERY, Toronto.

SITUATIONS WANTED.

ADVERTISER, shortly emigrating, seeks position as correspondence clerk and accountant. Well up in all details of engineering and allied business; ledger, balancing, shorthand and typewriting; excellent references. Lister, Ipswich Road, Ardleigh, Colchester, Eng.

ASSISTANT GENERAL MANAGER, McGill graduate, desires change of position. Twelve years' practical experience along engineering, machine, foundry and boiler shop lines. Best of references, Address Box 25, CANADIAN MACHINERY, Toronto. [3]

ENGINEER, Scotchman (33), single, all round millwright and draughtsman; been superintending constructional work and 9 years works manager of iron foundries; excellent references; open for anything in line; any part of Canada. Box 330, CANADIAN MACHINERY, 88 Fleet St. E.C., London, Eng. [7]

YOUNG man representing five large American manufacturers desires to make connection with a Canadian machine supply house or hardware firm wishing to open a mill supply department. Box 24M, CANADIAN MACHINERY, Montreal. [7]

Motors and Launches

I have the following new complete launches about ready for delivery:

Power Skiff, 20' by 4', fine finish, equipped with 2 h.p. Erd Motor, $190.00.

Launch, 22', 4'6" beam, cedar planking, turtle back deck, torpedo stern, equipped with 7½ h.p. 2 cylinder Erd motor, speed 10 miles an hour, $375.00.

Launch, 25' by 6' beam, cedar planking, quartered oak deck and coaming, equipped with 10 h.p. 2 cylinder Erd motor, speed 11 miles per hour, $550.00.

Erd motors from 2 h.p. to 30 h.p., from $65.00 to $600.00, also one 10 h.p. Buffalo 4 cylinder 4 cycle marine motor, as good as new, $250 00.

One 3½ h.p. Trebert, complete with reversing wheel, used only one season, $400.00.

One 6 h.p. Gillies stationary gasoline engine, cheap.

One 18' by 4'9" clinker built launch, equipped with 2½ h.p. Norwalk engine, launched Sept. 1906, speed 8 miles per hour, a bargain at $225.00.

$12.00 Per Annum Per Horse-Power

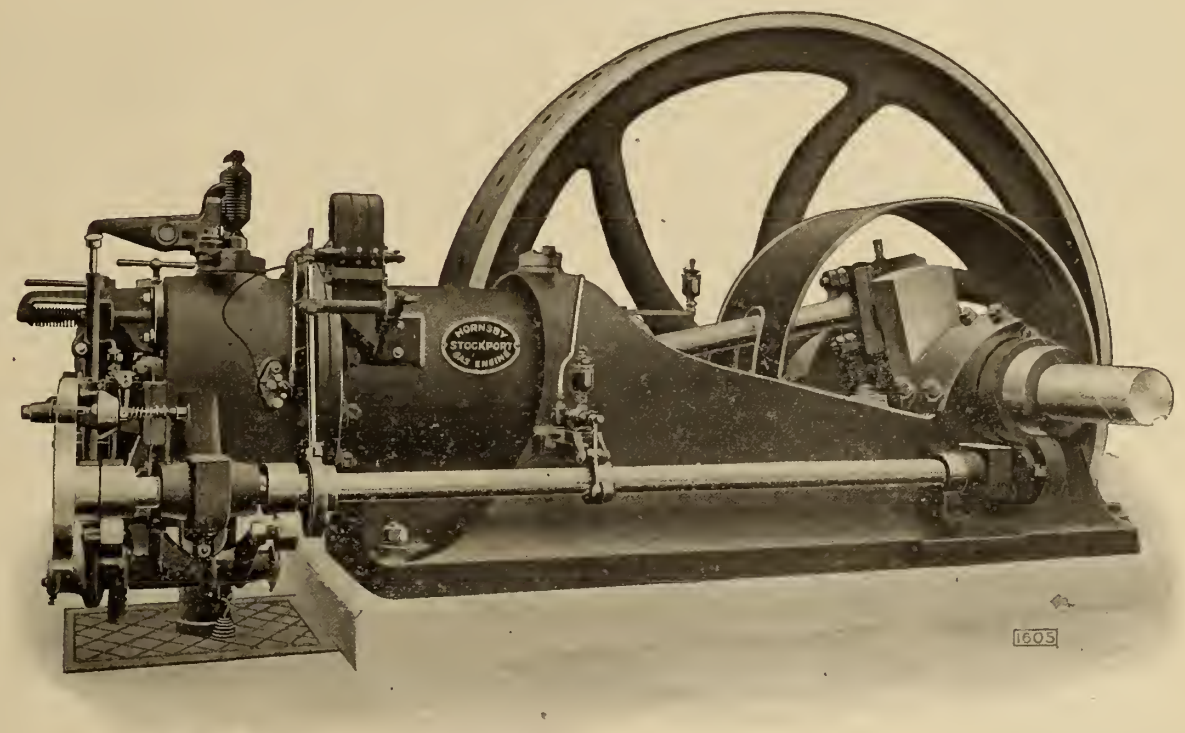
COLONIAL ENGINEERING COMPANY, Limited

222 and 224 ST. JAMES ST., - MONTREAL

SOLE CANADIAN AGENTS FOR

HORNSBY-STOCKPORT GAS ENGINES

(BUILT IN ENGLAND.)



150 H.P. Hornsby-Stockport Gas Engine.

NO odor. NO danger. NO pressure. NO smoke stack. NO steam boilers.

NO boiler feed pumps. NO feed water heaters, and NO complicated auxiliary apparatus.

IT generates its own gas in exact proportion to a varying load.

IT produces its own impulse exactly when required and not otherwise.

IT consumes, therefore, only an amount of fuel exactly in proportion to the actual power developed.

IT lubricates its own parts, pumps its own water, attends entirely to its own economy and gives absolute value for every ounce of fuel consumed.

Large equipments now being installed for several of the most representative manufacturing companies in the Dominion.

DOGGETT'S PERFECTION PARTING

GUARANTEED TO PERFECTLY PART
UNDER ANY AND ALL CONDITIONS

For Straight and Difficult Lifts Sticky Patterns Slanting Copes and Deep Chasings

Permits Swabbing and Slicking.

Will not Burn off the Face of the Mould, Wash or Cut.

SUITABLE FOR BRASS, BRONZE, IRON, ALUMINUM

Manufactured by

STANLEY DOGGETT

101 Beekman Street . New York City, U. S. A.

DISTRIBUTING AGENTS

DETROIT FOUNDRY SUPPLY CO., Windsor, Ont., and Detroit, Mich.

ALSO MANUFACTURE

CHARCOAL and CHARCOAL FACINGS
AND ALL GRADES OF SOAPSTONE FACINGS

Partine

THE UNIVERSAL PARTING

Trade Mark Reg. U. S. Patent Off.

A Popular Verdict

The only parting exhibited at the Foundrymen's Convention, held at Philadelphia, by actual tests is "PARTINE." With a practical demonstration in the presence of the visitors, the public became the sole judges of the efficiency of our product, whose superiority scored a grand victory, while we were highly complimented for the fairness of our dealings with the consumer.

Seeing is Believing

WE have the best article in the market, and as we are anxious to let the trade know it, we invite a thorough trial of "PARTINE" before placing orders.

SEND FOR SAMPLE AND BOOKLET

The following manufacturers of moulding machines used exclusively "PARTINE" for parting purposes in their exhibits during the Convention :

The Tabor Mfg. Co., Philadelphia, Pa.
Bonvillain & E. Ronceray, Paris, France
The Arcade Mfg. Co., Freeport, Ill.
The Macphail Flask and Machine Co., Chicago, Ill.

DO YOU DO IT?

When you read an advertisement that interests you, why not write the advertiser and get more information? It will help you to keep posted. Try it. The advertisers in **Canadian Machinery** will appreciate it.

WRITE THEM. TRY IT.

If you were at Philadelphia, you doubtless saw our Cleary Air Cooled Gagger Board and our Roller Bearing Sand Sifter

If you have air in your shop, you will find that a bountiful supply of gaggers will always be on hand and many a casting saved that is otherwise lost through lack of gaggers to hold up the sand.

For mixing facing or core sand by hand or power the Detroit Revolving Sand Sifter will do the work of four men. Did you ever think of making money this way?

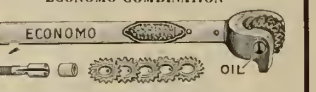
A Substitute for the Black Diamond

"ECONOMO"

ECONOMO COMBINATION



PRICE: Economo, $4.00 each; Economo Combination, $4.50 each.

Will true or shape any wheel except the very hardest and carborundum. The most efficient Roughing Dresser on the market—never gets dull from use.

Made of an abrasive nearly as hard as the Black Diamond. The Combination dresser is the roughing dresser placed in the "handle end" of the "Regular." It is made with corrugated tool steel discs and excels in wear and efficiency any dresser heretofore made. These tools are guaranteed satisfactory or money refunded. Sent on 10 day trial.

TOOL ROOM ECONOMY :—

The Use of Diamo-Carbo Emery Wheel Dressers.

The ***Diamo-Carbo Dresser*** is the only satisfactory substitute for the black diamomd. Permits you to true and shape your wheels just the same as with the more expensive device, and is adapted for use on all tool grinding wheels. The hardest abrasive known; wears indefinitely; and cannot get lost or broken and will not injure the edges of the most delicate wheels.

Made in three lengths: 8", 10" and 12" respectively.

Prices: $3.00, $3.50 and $4.00

Tell us which length is best suited for your needs, and let us send a Dresser on ten days' trial. Booklet and testimonials for the asking.

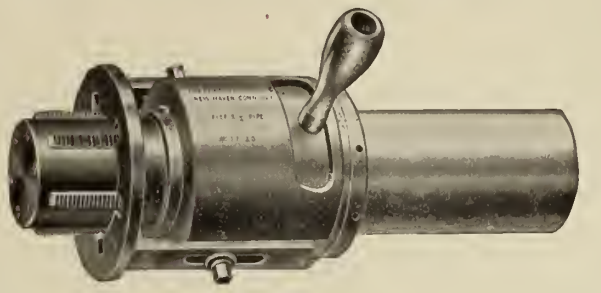
The Geometric Collapsing Taps

Save all Time of Backing Out.



After a hole is Tapped the desired depth, the chasers automatically recede, allowing the tap to be withdrawn at once. No time is wasted backing out and neither the Tap nor thread is liable to injury.
Considering this, will you keep on using the old Solid Taps?

TRY THEM IN YOUR SHOP.

The Geometric Tool Co., New Haven, Conn.

ENGINEERING:

AN ILLUSTRATED WEEKLY JOURNAL

Edited by WILLIAM H. MAW and B. ALFRED RAWORTH

PRICE SIXPENCE.

"ENGINEERING," besides a great variety of Illustrated Articles relating to Civil, Mechanical, Electrical and Military Engineering and Notes of General Professional Interest, devotes a considerable space in each issue to the illustration and description of all matters connected with the PRACTICAL APPLICATION OF PHYSICAL SCIENCE, and with its Wide and Influential Circulation in all parts of the world, this Journal is an

UNRIVALLED MEDIUM FOR ADVERTISEMENTS

SPECIAL NOTICE TO CANADIAN SUBSCRIBERS—The Publisher of ENGINEERING desires to call attention to the important reduction in the subscriptions for Canada. Owing to the new arrangements with the Dominion Post Office, the postage rate for newspapers is now 1d. per pound, and the annual subscriptions for ENGINEERING posted direct to Canada will, until further notice, be

Thin Paper Copies - - - - - -	£1 11 6
Thick " - - - - - -	£1 16 0

Subscribers residing abroad are strongly recommended to order copies on thick paper, as the illustrations are necessarily very much less effective in the thin paper edition, and to remit, when possible, by Post Office Order made payable at Bedford Street, Strand, London, W.C. When Foreign Subscriptions are so forwarded, advice should be sent to the Publisher.

Foreign and Colonial Subscribers receiving Incomplete Copies through Newsagents are requested to communicate the fact to the Publisher, together with the Agent's Name and Address.

Cheques should be crossed "Union of London and Smiths Bank, Limited, Charing Cross Branch."

All accounts are payable to "ENGINEERING, LIMITED."

ADVERTISEMENTS.

Prepaid Advertisements on Wrapper, **classified** under headings: Tenders—Appointments Open—Situations Wanted—Partnerships—Wanted, &c.—For Sale—Auction Sales—Publications—Miscellaneous—Patent Agents—&c.

By the Line—Four Lines or under, 3s., each additional Line, 8d. The Line averages Seven Words.

By the Inch—8s. per Inch Single Column, One Insertion.

5% *allowed on* 6, 10% *on* 13, 15% *on* 26, *and* 20% *on* 52 *Insertions.*

GUILLOTINE BAR SHEAR

Capacity for cutting off 12 x 1 inch Flat Bars.

We build three sizes of Guillotine Shears, capable of shearing 12 to 20 square inches.

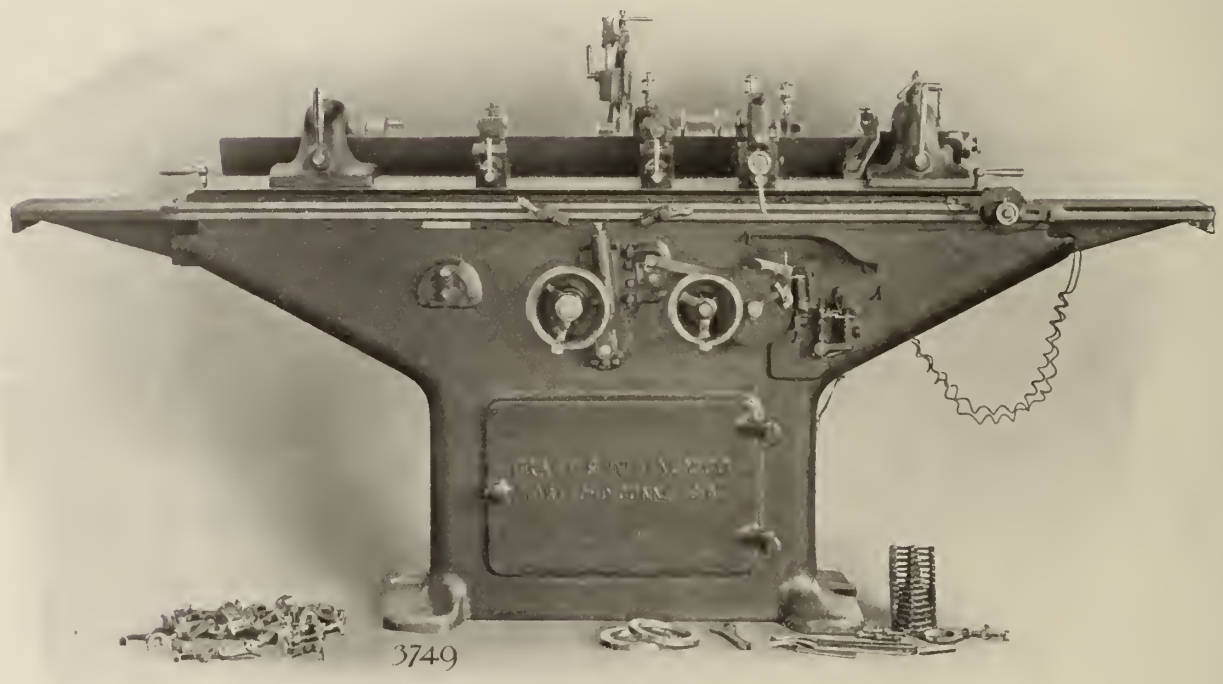
Our Catalogue describing the above line will be sent to any address on application.

THE JOHN BERTRAM & SONS CO., LIMITED

DUNDAS, ONTARIO, CANADA

The New Automatic Sizing Grinder

A perfectly developed machine for cylindrical work up to 5 inches in diameter and 48 inches in length.



New 5 x 48 Pratt & Whitney Automatic Sizing Grinder

Accurate Grinding with Unskilled Labor

The design is such as to produce accurate work without the attention of a skilled mechanic. An arm which rests on the work being ground is set with a micrometer screw to make an electric contact when the work is ground to desired size. The wear of the emery wheel has no effect whatever, as the machine will continue to feed until the electric contact is obtained. When work is nearly to size, machine changes to a very fine feed which is thrown out entirely when work is ground to exact size.

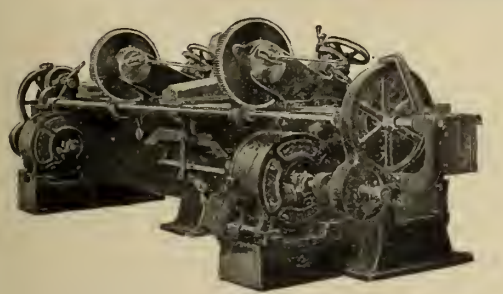
Westinghouse
Machine-Tool Motors



Westinghouse Type S Variable Speed Motors Driving Cincinnati Shaper Co.'s Double Transverse Head Shaper.

Electric drive applied to shapers and other reciprocating machine tools, meets with success because such tools must be driven up to their full limit at all times, as they are less productive than a rotary machine tool. The Westinghouse variable-speed motor is best for the purpose ; it has a wide range of speed control without sparking, giving the correct speed for maximum output at a high efficiency.

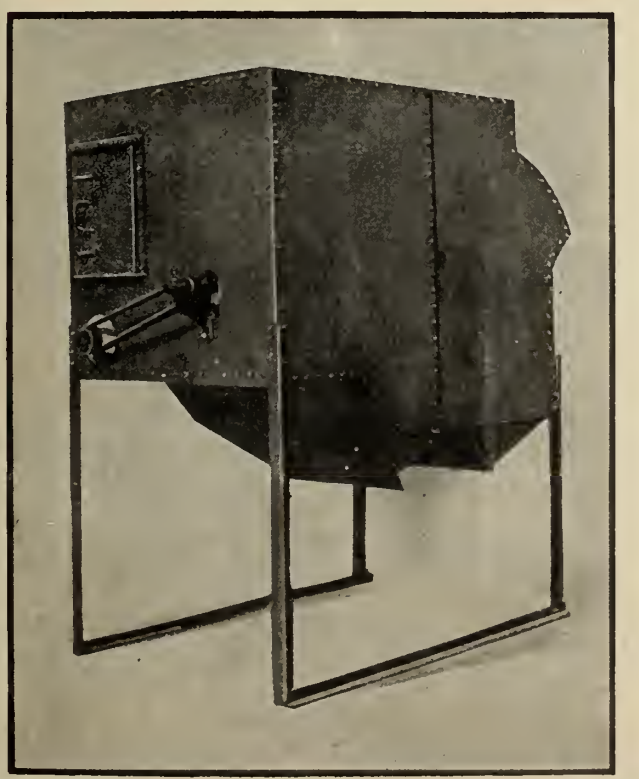
CORE SAND CLEANER

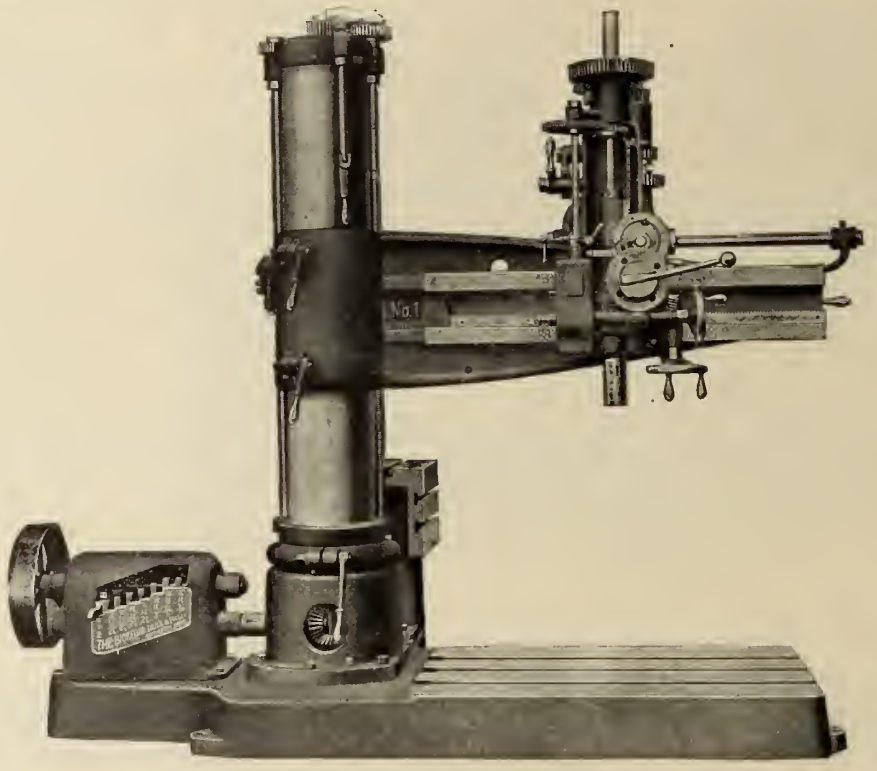


In many places core sand is expensive and hard to get. The cut shows our new core sand cleaner. This machine removes the fine dust and burnt bond from old core sand, and leaves the sand porous and ready for use again. By the use of this machine the sand may be used over and over continuously, by adding new sand to keep up the supply. Cores made of sand recovered by this machine are less liable to blow than those made of new sand, because the sand from old cores has been gassed off by the heat in former casts. It is self-contained and complete in itself, motor and fan inside out of the way and out of the dust. It is also portable. Four men can pick it up and carry it to any part of the foundry.

The W. W. Sly Mfg. Co.

CLEVELAND, OHIO

Our Latest and Best



Five years ago we brought out a line of IMPROVED RADIALS which to-day are known the world over. With this machine we introduced the SPEED BOX to the machine tool world and blazed a trail which has been followed by many copyists.

To this machine we have added .—

A TRIPLE DRIVING GEAR on the head, operated by ONE LEVER and placed between the tapping attachment and the spindle.

A SPEED BOX WITH EIGHT SPEEDS operated by ONE LEVER which in conjunction with the back gears gives TWENTY-FOUR SPINDLE SPEEDS.

FULLY 50 PER CENT. MORE DRIVING POWER which means the STRONGEST RADIAL BUILT.

We have retained the following well known valuable features :—

The dial depth gauge. The automatic trip. The range of eight feeds. The pipe section arm. The double round column.

WE HAVE ELIMINATED all friction driving clutches in the speed changing mechanism.

After a long series of tests of every description we now offer this machine in three sizes—4, 5 and 6 foot arms.

We are confident that, point for point, an unbiased comparison will convince you that we excel in the following essential features : POWER, DURABILITY, SIMPLICITY and EASE OF MANIPULATION.

Our 1906 Radial Drill Catalog tells the rest.

The Acme is a high-grade special tool, designed and adapted to the elimination of all unnecessary time in the manufacture of screw machine product. It has been proven the most economical machine tool in the market for the manufacture of duplicate parts from the bar.

The product of the Acme is as good as the best in quality, and far surpasses all others in quantity.

The Acme way is to produce a finished piece in the length of time required to perform the longest single operation.

Your enquiries are solicited. Estimates made on your samples will convince you of the economy of the Acme in your factory on your work.

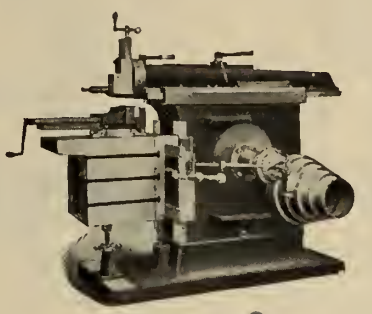
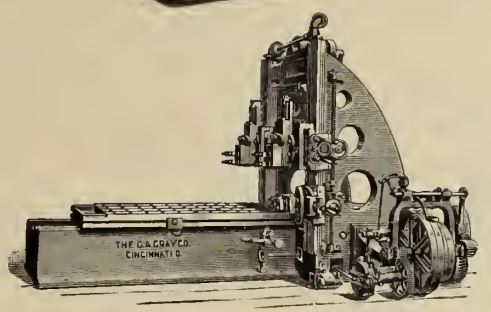
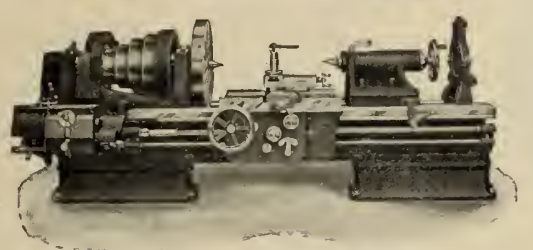
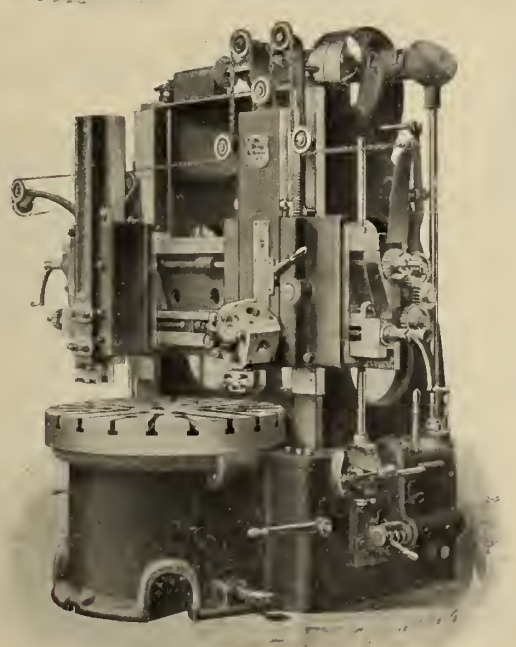
MACHINE TOOLS









¶ There are three general points to consider in buying a shaper :
1st. How much will it pull.
2nd. How fast will it pull it.
3rd. How long will it pull it.
These mean the tool's value to you as an earner. A careful study of the John Steptoe Shaper must convince you where to place your order.

¶ The G. A. Gray Co. plane their V's to a final bearing on Gray Planers. You'll admit that this is accurate work, yet V's should not need a scraper to get a bearing.

¶ Schumacher and Boye Lathes pull anything that high speed will stand, with ease. The three step cone gives a powerful drive without a single extra gear or patent change gear counter shaft to become noisy and offset the advantage gained in extra belt width.

¶ Are you familiar with what rapid production really means as applied to a Boring Mill? Write us about the King Mill.

How to Heat and Drive Steel Rivets

Awarded First Prize in Champion Contest at the Joint Convention of the International Railway Master Boiler Makers' Association and the Master Steam Boiler Makers' Association, held in Cleveland, O., May 21-23, 1907.

By James Crombie†

In riveting, no matter whether by hand or machine, there are several matters that must first receive attention before any rivets can be driven or a satisfactory job made.

We have first the assembling of the work. The plates must be bolted together and all the rivet holes reamed out to correct size, i.e., 1-16 inch larger than the size of rivet to be used. Reamers are made with about 3 inches of tapered end and 4 inches of straight section for each different size of hole. This insures that the hole will be parallel, or the same size all the way through. After reaming, the work should be taken apart and all burrs and pieces of cuttings left between the plates by the reamer scraped off and the two surfaces made perfectly clean. The outer sides of holes should also be gone over with a broad countersink drill to remove the burrs from the edge of the hole. The work should then be bolted up close and any joints warmed and closed up with hammers or squeezed in the hydraulic machine.

Rivets.

Rivets should be of best quality of open-hearth steel, extra soft grade, ultimate strength 45,000 to 55,000 pounds, elastic limit not less than one-half of the ultimate strength.

$$\text{elongation} = \frac{1{,}400{,}000}{\text{ultimate strength}}$$

maximum phosphorus .06 per cent., maximum sulphur .04 per cent.., cold and quench bends 180 degrees flat on itself without fracture on outside of bent portion. On being nicked and broken off the steel should be of a light gray color, showing a close-grained, silky fracture. A course-grained, dark-colored rivet steel should be looked on with suspicion, as the chances are that after being riveted up the rivet head will drop off. Excess of sulphur or excess of phosphorus will make the steel "short" or brittle, causing the rivets to break. We had a lot of trouble with one consignment of rivets. After being driven the heads or points of a large percentage of these rivets would drop off, not immediately after being driven, nor when the plate edge was being calked, but 4, 5 or 10 hours after they were finished. Some of these broken rivets, 4 inches long, were backed out of the hole, they were bent 180 degrees on themselves cold without any sign of fracture. The trouble was apparently excess of phosphorus, causing segregations in spots in the steel. Where these spots were the rivet would break off easily and the material was very brittle. These rivets went into the scrap heap in double-quick time.

Heating the rivets does not depend so much upon the kind of fire or fuel as upon the rivet heater. Given a good, willing heater, and no matter how adverse the conditions are, he is always there with a good hot rivet and the work goes swinging along. Good work can be obtained from a coal or coke fire, either with a side or bottom blast. There is always the danger in these fires of overheating the rivets, or they may be left in the fire too long while the squad is changing or during the meal hour. The rivets will then have a heavy scale whether it will be best to leave them in. I believe in having them out if at all possible, either by cutting off the heads and backing them out with a punch and on them and be wasted, becoming too small to fill the hole properly; this should be avoided.

Rivets that are sparking hot or show signs of overheating should be discarded. If such rivets should be driven through any mistake or any heads show signs of being burnt on examination after the job is finished, the question arises, whether more injury will be caused to the plates by cutting those rivets out or hammer or drilling them out. There should be no danger of burnt rivets, although if too many rivets are put into the furnace at one time and the work is lagging behind, the rivets will quickly get scaled and waste.

I have got good results from an oil furnace with any baffle brick, using pitch oil and allowing the flame to blow right on to the rivets. This was principally on large sized rivets. I believe that the best results are obtained from a good

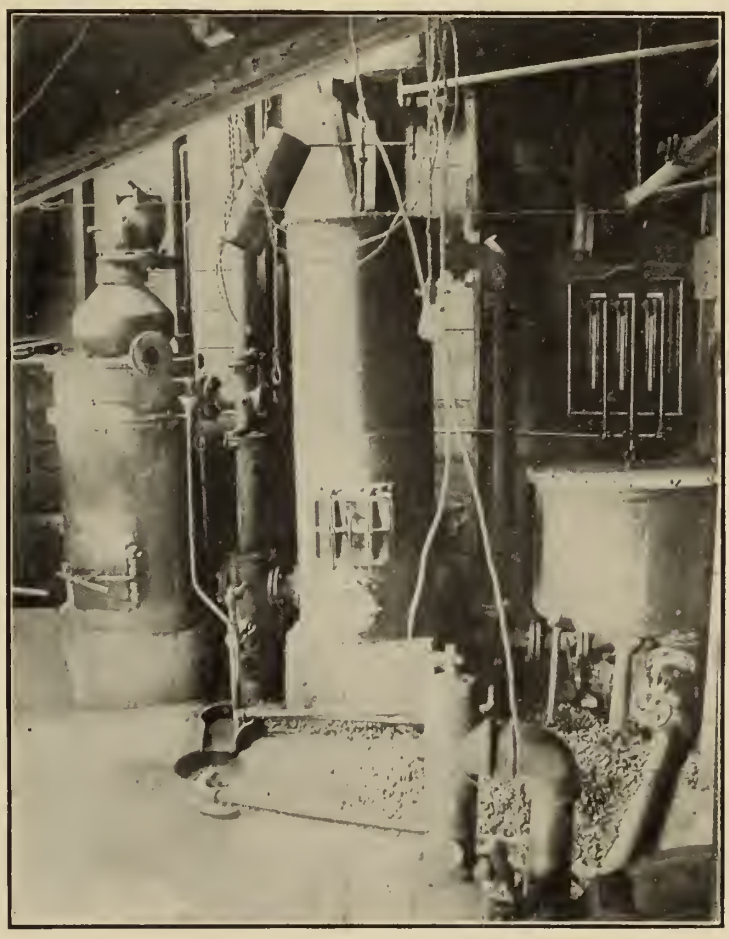

Illustration of Producer Gas Plant, the economy of which was spoken of in the article on Producer Gas in the July issue, by Emil Stern. This is a Pintsch Plant installed by the Economic Power, Light & Heat Supply Co.

† Foreman boilermaker of Sawyer & Massey Co., Hamilton.

oil furnace with a baffle-brick or fire wall using compressed air. We use oil rivet forges burning fuel oil, or gas oil with compressed air, and get nice, soft rivets, just a bright cherry red or white-hot if desired. This style of forge leaves nothing to be desired. It has a fire-wall, heats rivets quickly, and does not cost much to run. The oil and air is mixed before entering the furnace, and then passes through a small opening at the side of the furnace. Combustion then takes place, the flame striking the baffle-brick or fire-wall, then passing over the top of the fire-wall and heating the chamber where the rivets are. The heat then radiates from the top down upon the rivets.

Rivets that to be driven by hand or by an air hammer require more heat than rivets for the hydraulic riveter. A cherry red will be best for a hydraulic machine, but for an air hammer or hand riveting the rivets should be a light yellow, turning to white, but not sparking. That would be about 1,500 degrees F. for hydraulic and 2,000 degrees for hand-driven rivets.

Machine Riveting.

There are several kinds of machines for riveting. I have seen good riveting done on an old steam riveter, each rivet receiving from two to three blows. This style of machine has gone out of date and is seldom seen now.

We have our good friend the hydraulic riveter or "Bull." This machine may be considered ideal both as to operation and effect. The water is supplied in pipes at a pressure of 1,500 pounds or more per square inch. In the best class of machines the pressure is delivered through different valves, so that the operator has control of the pressure at all times, reducing or increasing the pressure according to the size of rivet. The best pressure is 100 tons per square inch of rivet section. The water, after the rivet is squeezed, passes back to the tank again, and is used over again, so that there is very little waste of water. The full pressure is available throughout the full length of the stroke, so that the rivet is properly upset, thoroughly filling the hole from end to end, and also squeezing the plates close, holding them for several seconds while the rivet is contracting or cooling off.

For heavy work, the machine should have a plate-closing device, so that the plates can be held close together before any pressure is applied to the rivet, the rivet dies being controlled by separate levers and working in the centre of the plate-closing device yet separate from it.

A good hydraulic crane is best suited for handling the work at the riveter. It is quick in action and very sensitive, and the hole is quickly centred with the rivet dies. All levers should be handy for the operator, the same operator controlling the levers for both crane and riveter. The work should be hung fair. A little time spent on this will be gained later on and temper saved, too.

After the work has been cleaned and bolted up it is squeezed up and all the bolts tightened. The boiler should then be tacked at each quarter, then at each eighth, and afterwards at every third or fourth hole. The remaining rivets are then driven, going right along around the boiler, allowing the full pressure of the machine to remain for a few seconds on each rivet as it is driven. At the longitudinal seam or butt-joint the end should be tacked first, to prevent springing, then at the centre, after which the rivets may be driven in succession. The operator should be given to understand that it is not the number of holes he can fill up, but the quality of the work on the testing floor that counts. The danger to be looked for is the crushing or scalloping of the plate in front of the rivet, through excessive pressure or through too much being planned off the plate edge. Also the point may fail by not being properly proportioned, by the plate breaking along the line of rivets by the shearing out of the rivets or by the shearing of the plate in front of the rivets, and if the work is not hanging fair the rivets may be driven offside, thus necessitating cutting out.

All rivets should be put into the holes from the outside, as it is much quicker and requires a man less on the job. A man inside the boiler is apt to get hurt, too.

There is also the pneumatic lever type of machine, the hydro-pneumatic type; the pneumatic toggle-joint machine giving a full pressure only at end of stroke, and the portable hydraulic type similar to the "Bull." The latter is handy for riveting around the ends of boilers or furnace mouths, or around the flanges of flues in Lancashire or Cornish boilers. The water, after it is discharged from this machine, does not return to the tank as in the fixed riveter, but is conducted through a rubber hose to the nearest sewer. This type is wasteful as regards water.

I pin my faith on the hydraulic riveters, as first-class work can be obtained from them. The rivets do not require such an intense heat, therefore there is no risk of burnt rivets, and there need be no guess work about the pressure applied to each rivet.

I use high-speed air hardening steel for rivet dies on the "Bull." The initial cost is high, but they are all right. I have driven 180,000 rivets with four pairs of dies made from this steel, and they have not been to the tool room since we started to use them. They are still sharp on the edge and are only beginning to show slight signs of wear. The most that can be got from a pair of ordinary cast steel rivet dies is about 4,000 rivets, while these, I believe, will average 50,000 each.

Another good riveter is the air hammer or "Gun," working with compressed air at a pressure of 80 to 100 pounds per square inch. With this machine a careless riveter, or one wanting to make a show, may drive a short rivet, too short to properly fill the hole, merely blinding the work by allowing his hammer handle to describe a large circle, thereby spreading the rivet instead of allowing it to upset into the hole. If there is enough stock in the rivet and the rivet is driven fair into the hole, these hammers will give a good tight rivet that will not require calking. With the air hammer it is necessary to hammer up the plate in front of the riveter and to have the work all thoroughly closed up, as there is no squeeze as in the hydraulic machine.

Hand Riveting.

In work to be riveted by hand it is better to have all holes countersunk The countersink must be narrow and deep, from 1-16 to 1-8 inch of the bottom of the hole in the first plate, then if corrosion or wasting occurs the rivet and plate will both wear equally and the strength of the rivet will not be impaired. Where a shallow, broad countersink is used there is more chance of the rivet breaking off than where a narrow deep one is used. The rivets may be snapped by hand, but this practice has gone out, as the rivets are not so reliable as when countersunk.

The best practice is to finish on the third rivet, that is, we have our squad all ready to start with hammers, the hole is hammered close and the first rivet is put in and hammered down but not finished, the second hole is plied close, the rivet hammered down as before, the same with the third and fourth. The fifth rivet is then put in, the sixth hole plied close and our squad goes back to the third rivet, giving it a few heavy blows, then finishing it off with their riveting hammers. Thus they work right along, always finishing on the third rivet back.

The Holder-on.

It is hard to give any hard and fast rule regarding holding up the rivets, as there are so many different classes of boiler work and so many different tools to be used around a boiler in holding up. We have our dolly bars and water-space hammers, and also long-handled hammers, supported on a hook. Where possible it is best to use the compressed air holder-on. In all these things we must be guided by circumstances, always endeavoring to get the head well up or the rivet will not be tight.

Opinions Concerning "Ashes Burning"

"Cannot burn ashes," says C. S. Miner—Coal in ashes only that burns—Better to screen ash pile than to use brine and acid solution—Formula probably useless.

In these days the motto is to waste nothing. It is proverbial that in the pork packing industry nothing is lost but the squeel. There is the same tendency in all other industries. A striking example of this principle is evidenced in the by-product producer gas plant. No wonder then, that, when the cobbler in Altona, Pa., published his ash burning formula, the whole country was stirred! Thousands of tests were made by householders and others with results which led many to pronounce the scheme a success. From the first chemists and those acquainted with the laws of cumbustion scouted the idea that there could be anything in the scheme, but these opinions carried not much weight in the face of the many experiments which showed that the mixture as prescribed would burn. But few records of tests made upon a common sense, commercial basis, were published; but the few that were showed that not only was there nothing to be gained, but that the salt and acid in the mixture might play havoc with the iron grates.

For the benefit of the readers of Canadian Machinery, some data on this subject has been gathered which shows the trend of opinion among those who would be chiefly affected by this scheme.

It was not until shares in a company formed to manufacture a compound which, when mixed with one part coal and two parts ashes, would produce from 50 to 150 per cent. more heat than could be secured from the best coal, that the United States Government took any notice of the affair. But when this absurd propaganda was brought to light, there was need for investigation. Following is a report made by Carl Shelby Miner, Director of the Miner Laboratories, Chicago, upon the question:

Silver Mines, Port Arthur—Cut Loaned by W. G. MacFarlane.

Statement by Director of Miner Laboratories.

"Let me begin the discussion by stating explicitly that you cannot burn ashes. Ashes are a mineral matter which has absolutely no fuel value. Ordinary ashes, however, contain a small amount of unburned coal, and this coal can be burned under proper conditions. Ashes and coal are of variable composition, but, for the purpose of this discussion, we will assume that ordinary hard coal contains 10 per cent. of ash, by which we mean absolutely incombustible material; and the ashes from a well-regulated furnace contain 25 per cent. of unburned coal, which is a liberal estimate. There would then remain 13 1-3 per cent. of "ashes," of which 3 1-3 would be coal and 10 per cent. genuine ash. Therefore, the loss if these ashes are thrown away is 3 1-3 per cent. of the coal used. In the form of a table this statement appears on the following page.

"So, if we admit that this method will enable us to burn all the coal in the ashes, and that is the limit of its possibilities, we may hope to save 1-33 per cent. of our coal bills. The advocates of this formula cannot claim that it

contains any heat-producing material except the oxalic acid, and that is present in so small a quantity as to be negligible in making this calculation. The water and salt have no fuel value. There is, therefore, absolutely no basis for the claim that ashes and coal mixed with this compound are a better fuel than coal alone.

"This is not by any means the first attempt to produce a compound that will increase the combustion of coal in stoves or furnaces. Some years ago a combustion powder for this purpose was exploited in Germany, which appeared to be a great success, for when it was thrown into a fire the flame brightened up at once and appeared to burn more briskly. The unsympathetic government chemists, however, analyzed the powder and, finding it to be only common table salt, branded the whole thing as a fake. The salt is retained in the present formula. There have, however, been formulae devised more satisfactory than that one. The basis of all of them is some material which will release oxygen, the gas necessary to promote combustion, in close proximity to the coal in the ashes. This result is obtained by mxing the ground ashes with the compound before putting them into the furnace. In the cobbler's formula the oxalic acid is probably intended to furnish oxygen. It contains oxygen, but it also contains carbon and hydrogen in amounts more than sufficient to combine with its oxygen, and it therefore uses up oxygen instead of furnishing it. The water is the only constituent of any possible value in this formula. It is composed of hydrogen and oxygen and at high temperatures breaks up into these two gases and so might furnish oxygen for the combustion of the coal in the ashes with which it has been mixed.

"The scheme of mixing water with ashes to burn coal out of them has been known for years and has been used by householders all over the country. It is covered by a United States patent for "a method of producing complete combustion of the mixture." Comparative tests made with ashes mixed with water and ashes mixed according to the cobbler formula show practically identical results. In both cases there was left about 7 per cent. of unconsumed coal in the ashes. It therefore seems clear from both theory and practice that there is no new and useful improvement covered by this formula, but it is, as rehashing of an old and time-tried method.

"The probability is that neither method has any real value, but that the results obtained are due entirely to the repeated burning to which the ashes are subjected. It is reasonable to assume that if the ashes are fed back into the furnace often enough, with plenty of fresh coal, the coal in them will eventually be consumed."

There is a statement by a man who should know. Ashes cannot burn. All that can be done is to consume the coal that is left in the ashes, and C. S. Miner expresses the doubt whether the salt and oxalic acid assist the combustion to any great extent.

Opinions of Canadian Manufacturers.

Opinions on this subject from some large coal consumers in Canada were sought by Canadian Machinery. These speak for themselves:

Walkerville, July 10, 1907.

Canadian Machinery,
10 Front St. east, Toronto, Ont.:

Dear Sirs,—We acknowledge the receipt of your favor of the 5th instant, and in reply thereto we would say that we have not experimented in any way with the ashes burning scheme referred to. We have, however, noticed several articles in connection with the matter in the daily press, and we are inclined to think that there is very little advantage to be gained by adopting the system.

Yours very truly,
Hiram Walker & Sons, Limited.

Montreal, July 10, 1907.

Canadian Machinery,
Toronto, Ont.:

Gentlemen,—We duly received yours of the 5th inst., and in reply to your inquiry would say that we have given very little consideration to the question of burning ashes, as the problem with us is to so consume our coal that all the ashes left therein would not be worth thinking about, and that is without doubt the case with us at the present time, as the percentage of coal, or carbon, in our ashes is infinitesimal; further, would say that we have no faith whatever that any mixture of salt, etc., is of the slightest use—in fact in our opinion it is a detriment.

From this you will understand that, in our opinion, if any concern has a large percentage of coal in their ashes the cheapest and most economical way for them to do would be to sift the coal out and thereby save a lot of trouble, labor and waste of good coal in heating up ashes and clinkers.

Yours very truly,
The Dominion Oil Cloth Co.,
Limited.

Toronto, July 12, 1907.

The Canadian Machinery, City:

Dear Sirs,—Your favor of the 5th was duly received, in reply beg to say, we have not made any tests of the schemes you refer to. If you know of anything that is of any material value we should be glad to hear from you.

Respectfully, yours,
The Otto Higel Co., Limited.

Hamilton, July 17, 1907.

Canadian Machinery, Toronto, Ont.:

Gentlemen,—In the burning of bituminous slack there is always a certain amount of loss of good coal due to its falling through the grates with the ashes. These ashes mixed with one part of good coal, then moistened with salt water, into which has been added a little oxalic acid, will give an intense heat when thrown on top of a good fire. The result is the formation of a layer of molten slag over the top of the fire, which completely cuts off all draft and deadens the fire, necessitating cleaning after each firing. This, of course, is a great drawback and prevents the practice being carried on under a steam boiler.

It was our intention to make tests on sample pieces of steel plate, placed in the smoke flue and among the tubes, to determine whether the products of combustion given off by the ash mixtures had any corrosive effect, but owing to the difficulty of keeping up the fires due to the above mentioned cakening of the ash mixture, we were unable to carry the experiment to a completion.

Yours truly,
Canadian Westinghouse Co.
Limited.

Toronto, July 6, 1907.

Messrs. Canadian Machinery and Manufacturing News, 10 Front St. east, city.

Dear Sirs,—Yours of the 5th inst. received in reference to burning of ashes. We think the idea a good one so far as a steady warm fire is desired—not one that is to be pushed.

We find that, in the use of the ash-burning material, it is a considerable advantage as, while the ash itself is dead, there is a large quantity of cinders which, with the process, one is able to obtain a most satisfactory fire for steady purposes.

Yours truly,
The Canada Metal Co., Limited.

Coal contains—			
Combustible material			90 per cent.
Incombustile material or ash			10 per cent.
Ashes contain—			
Combustible material	25 per cent.,	equivalent to	3 1-3 p.c. of coal used
Incombustible material	75 per cent.,	equivalent to	10 p.c. of coal used

Hamilton, July 6, 1907.

Canadian Machinery, Toronto, Ont.:

Dear Sir,—In reply to your letter of the 5th inst. we would say that we have made no experiments with burning coal ashes which amount to anything.

Yours truly,

The Hamilton Steel & Iron Co., Limited.

Toronto, July 11, 1907.

Canadian Machinery, 10 Front St. east, Toronto:

Dear Sirs,—Your letter of July 5th to the Canadian General Electric Co. regarding question of test of ash burning has been referred to me. In answer would say that at the works of the Canada Foundry Co. we have made no experiments to test the efficiency of this scheme.

Yours very truly,

Canada Foundry Co., Limited.

Our Water Powers; Falls in Current River Park, Ont.—Cut Loaned by W. G. MacFarlane.

Experiment Showed Loss of 15.9 Per Cent.

The test made by R. C. Harris, City Property Commissioner, Toronto, was very complete, and was conducted upon a sound basis. This was an evaporative test under one of the boilers in the City Hall. The following is a record of test as given by Mr. Harris:

"Three thousand one hundred and fifty-six pounds of slack were mixed with 2,441 of ashes, the whole being saturated with 51 gallons of water, in which were dissolved 25 pounds of common salt and two pounds of oxalic acid. The fuel was fired automatically by an underfeed stoker with forced draft. During this trial the average gauge pressure was 73, but fluctuated rapidly between 65 and 80, and it was only by continuously driving the fan supplying the draft that we were enabled to hold the steam at this average. It was apparent that good combustion was not taking place, inasmuch as the top of the fire was at all times far short of incandescence. The ash in the mixture packed, with the result that the air supply requisite to properly support combustion was deficient. At the conclusion of the test there was no apparent detrimental affect on boilers and grates.

"In the second trial, firing straight bituminous slack by means of underfeed stoker with forced draft the average gauge pressure maintained was 83, with scarcely any fluctuation, the fan being driven but a portion of the time.

"The cost of evaporating 1,000 pounds of water from and at 212 degrees F. with the ash admixture and chemical solution was 20.62 cents., while in the second test, with coal only, it was but 17.78 cents. This shows that to evaporate 1,000 pounds of water from and at 212 degrees F. with the mixture of coal, ash and chemical solution it costs 2.84 cents more than with the coal untreated, demonstrating a loss of 15.9 per cent. in the use of the treated fuel. If further allowance were made for the additional amount of steam needed to continuously drive the fan in the first test, the loss would be considerably greater.

"We found that it was absolutely impossible to hold the steam with a preparation of one part of coal to three of ashes. It was also necessary during the run to at times replenish the fire with coal unmixed with ashes. The indications throughout the whole of the test where the fuel was mixed with ashes were altogether unsatisfactory."

Prof. W. H. Ellis, professor of applied chemistry in the School of Practical Science, University of Toronto, laughed to scorn the idea that ashes burn. He said, "it is an absolutely fixed equation that ashes, or the residium left after complete combustion, have no heating power whatever, and no possible treatment can make them produce heat, whether in conjunction with fresh coal or otherwise."

CANADIAN SECURED THE PRIZE.

In this issue of Canadian Machinery there appears an article entitled: "How to Heat and Drive Steel Rivets," by James Crombie, foreman boilermaker of the Sawyer & Massie Co., Hamilton. The article was awarded first prize at the recent joint convention of the International Railway Boiler Makers' Association and the Master Steam Boiler Makers' Association at Cleveland, for which he received $50 in gold. Mr. Crombie is to be congratulated, and his friends and fellow Canadian mechanics feel proud of him.

Very often the men who are in the best position to impart information along mechanical lines, so far as the information itself is concerned, are handicapped by lack of ability to express themselves clearly. When a man has information which is valuable and knows how to impart it, he is fortunate.

A great deal more writing upon mechanical subjects has been done in the United States than in Canada. The demand, made by publishers of mechanical papers and mechanical books in the States led to the development of many writers. In Canada this has not been so to the same extent. Therefore, all the greater credit is due a Canadian when he wins in such a game against American competition.

To the inexperienced, describing some article, telling about some kink, or writing an article on some mechanical subject, comes rather difficult at first, but upon some little practice comes more naturally. It is surprising how one can think he knows a lot about some particular subject or thing, but upon attempting to write concerning it, he often finds himself quite uncertain of many details. Writing is a splendid education in that it teaches one to make thorough investigation to get at all the details before forming opinions in his own mind concerning it. It's a splendid thing to read, but a better thing to write.

In practically every little or big shop in Canada, there must be devices which have been originated in that shop to do some special job or to act as a substitute for something not contained in the equipment of that shop. Why should not somebody in these shops assist himself and others by making sketches of such devices, writing a short description of them and their uses and having them published? Canadian Machinery is always looking for just such material. The remuneration received for such contributions would pay amply for the time spent, and there would be the additional satisfaction of knowing that one was educating oneself, and at the same time helping some fellow mechanic out of a tight place by the suggestion.

JULY METAL MARKET.

Throughout the past month has ruled the usual dullness characteristic of the midsummer season, although there have been one or two exceptions. During the earlier part of July the metal market was quiet, but about the 15th a revival came in the demand for iron and steel. The foundries did not remain idle as long as

was expected, since those companies who were awaiting shipments from Europe, which, in a number of cases, were fulfilments of orders given two months previous, were anxious to take advantage of the prospective enlivening of the market. During the week commencing July 15, arrivals of cargoes aggregating between 7,000 and 8,000 tons of iron were reported. It was not long before this heavy tonnage was distributed.

The English iron market has been subjected through the month to many fluctuations, caused in many cases mostly by speculation. In the first week of July prices were weak and little call was experienced. The next fortnight registered a strong recovery, and again, now, there are indications of a relapse. The American market has been dull throughout the month.

Ingot tin has been steadily weakening. The corner in the London market which held up transactions for some time was broken in the middle week of July, and since then prices in the English market have steadily declined from £18 to a minimum of £8. Premiums have been greatly reduced and local market conditions are in a much healthier state. The ruling price for Lamb, Flag, and Straits tin in the local market during the month has been $44.

With the arrival of H. H. Rogers, the copper king, at New York City, about the 1st of July, the tension existing in the American copper market was broken. Much uncertainty had existed previous to Mr. Rogers' arrival, and little buying was done. Prices were immediately lowered and the call rapidly increased.

Supplies in the local market throughout July have been adequate to the call, which was small, owing to the uncertainty which ruled despite the amelioration in American conditions.

Much confidence is expressed by dealers in the probability of immediate enlivenment of business. Hopefulness is the general attitude at present.

PROGRESS OF PRODUCER GAS.

Undoubtedly there is economy to be secured with producer gas plants and engines. It is not now all hearsay and manufacturers' claims in Canada, as it was three or four years ago. There are many plants now in operation in Canada, and manufacturers or users of power who are thinking of installing plants can see for themselves exactly what producer gas plants are doing.

Not all the plants, which have been installed in Canada, are operating as satisfactorily as claimed in the catalogue of the manufacturer, but there are now a sufficient number installed which are giving excellent satisfaction to prove that the producer gas plant in general is not at fault, but that, in a case where a plant does not operate satisfactorily, the fault lies with the operator or with the design of that particular patent.

When one sees the volt needle swinging to the tune of 25 or 30 volts every few seconds in the power line from a dynamo operated by producer gas engine and plant, one naturally thinks that the engine governor must be off on a "hunting" trip; but when one peeps into the gas generator and notes that it is about half full of fuel, and sees the gas burning above the fuel bed, one no longer blames the engine governor, but the engineer in charge of the plant; when, however, the engineer tells you that if he fills the generator with fuel, as it should be, the engine stops from lack of gas, one would lay the blame to lack of gas space in the generator, but hesitate, lest you again make a mistake. Then one arrives at the safe conclusion that something is wrong with the design of the gas space or other part of the generator, or that the engineer in charge does not know his business. Then one wonders that the company who made the installation does not have a thorough investigation before its reputation in the producer gas plant line is damaged.

But, as was said before, such an occurrence does not reflect discredit upon producer gas plants in general.

For the benefit of manufacturers who may be interested in producer gas plants we hope to publish next month illustrations of several producer gas plant installations in Canada together with necessary description of the plant and engine, and as complete a record as possible of what a manufacturer is chiefly interested in, namely, fuel consumption under ordinary running conditions, attendance required, amount of cleaning necessary and other minor points about the operating of the plant which may be of interest.

OPPORTUNITIES IN BUILDING CONTRACTORS' MACHINERY.

While at the present time there are big opportunities for building up a manufacturing business of almost any kind in Canada, yet there are special opportunities in some lines. One of these appears to be the manufacture of contractors' machinery. Building is the first industry affected by the rapid growth of a country. Now the builder and contractor uses a great deal more labor saving machinery than he did a few years ago. There will be an immense amount of this machinery needed for many years to come. There is a large field for a firm in its manufacture.

The working up of such a business can well be started in a small way—in fact in a repair machine shop and foundry. A start is the repairing and job work for local contractors and builders. Good work is done—more and more work is dug up—great perseverance is shown—the horizon broadens—a bigger and better equipped shop is necessary—the firm is on its way to prosperity.

A business we have in mind was built up just in that way. Now the firm have one of the largest and most modern plants in Canada. Another we know has made a start. Two progressive young fellows are at the head of it. They are looking for the gradual development into a large business.

Concerning Tool Rooms*

A Practical Tool Room System for an Average Size Shop, such as the Writer has seen in Successful Operation.

BY Geo. D. MacKinnon, B.A. Sc.

ARTICLE II.

To facilitate the settling up with men quiting work as well as to reduce the time of the one who may have to look up their checks, it is very desirable that the checks be located on properly arranged check boards, instead of being scattered on pins all over the room; and it is a good plan, and a convenient one, too, for the tool window tender to have all these check boards located within his reach near the window. It is surprising the number of tools that can be checked for on a small board. Such an arrangement may consist of twelve boards, and these can be arranged systematically so that a minimum of time is lost in looking for or placing a check; and this also reduces the time lost by a man returning a tool since his check can be handed to him immediately instead of him having to wait until the tender walks down the room to the tool case and back again, such as would occur if the check were placed on the case in which the tool is kept.

Damage to Tools Should Be Reported.

It frequently happens that tools are destroyed in service, sometimes through accident and sometimes through carelessness. The former is for the most part unavoidable, although the number of so-called accidents would be considerably reduced by strict attention to business; but one must expect a certain amount of carelessness since one cannot expect that every man in the works will take a deep interest in the work he is doing; and lack of interest is akin to carelessness.

It is one of the objects of the shop superintendent to keep his operating expenses as low as possible, consistent with efficiency; and in the matter of damage to tools, machines, etc., he can be greatly assisted by the tool room. Various methods are suggested for the cutting down of this portion of the shop expense, and one very satisfactory way is to have the attention of the superintendent or manager drawn to the facts of these damages. A convenient way of doing this is to have the man who does the damage report the same on a special form, such as Fig. 2. This form is obtained from the tool room, is filled out by the workman, signed by his foreman, and returned with the broken tool to the tool room. The tool room foreman notes the extent of the damage, the probable cost of repair, etc., and each morning all reports of the previous day are sent to the manager's office for his disposal.

When and When Not to Dock for Broken Tools.

The writer does not advocate the principle of docking a workman's wages for damage done if said man is working on an hourly rate, except when the damage is done through gross carelessness; but such a policy is worthy of consideration when a man is on a piece rate and is pushing his machine for all it will do. But in such a case an understanding should be arrived at with him when he is starting on his piece rate. But dock or no dock, the mere fact of the damage being brought to the attention of the manager and entered against the man's record, is generally sufficient to reduce carelessness to a minimum.

Record of Damage Should Be Kept.

Records should be kept in the tool room of all damage done, and in a shop of this size it requires a very small amount of the foreman's time to

record such damages. In the matter of small tools it is sufficient for all purposes to enter the damage in day-book form, totalling up at the end of each month. But in the case of machine tools a card system is desirable. This may have the form of Fig. 3 (front and back), one card being used for each machine. When it becomes necessary to purchase a new machine it does not usually take a manager long to decide after looking over these card records,

REPAIRS

Date of Break Down	Repair Completed	Cost of Repair	Extent and Nature of Damage

Fig. 3.

of the most economical make; and such a record is a valuable one.

Window Tender Should Be Capable Man

We often find that the man who has been given the position of window tender is one who is content to draw the pay usually allotted to an ordinary laborer. I have no hesitation in saying that the employment of such a man in such a position is a dead loss to the company; and the one who holds this important position should be a capable mechanic. He should know when a tool is or is not suitable for the work intended; and he should be able to "fit up" tools for those requiring them without it being necessary for the man wanting the tools to explain to him just how they should be fitted up. The writer has frequently seen a crowd of highly paid mechanics standing at a tool room window waiting to be served, while the attention of the man behind the window —who by the way was drawing 12½ cents per hour—was taken up by one of the number endeavoring to secure a tool suitable for his job, which tool might have been given to him at once by one who himself had had experience along those lines. It is an easy matter to figure the loss to the company under such circumstances.

Check System for Tools Used in Erecting

Shops which do any amount of outside erection work, know what a loss there generally is through the losing and destruction of tools, tackle, etc. When one figures it out the extent of this loss is often surprising, and so long as the men are allowed to pick up tools, etc., indiscriminately, pack them up and take them out of the shops without any check on them, so long will the loss be large. It requires very little time to fill out a form such as Fig. 4, which is left with the tool room foreman as a receipt for the tools, and checked off by him when they are returned. Since the erecting engineer knows that the people at home are interested in the tools which he has out he is more apt to take care of them and to see that they are all gathered up before he starts for home.

should be given, for it is not at all uncommon to see all sorts of tools piled up in a case without semblance of order. Needless to say, it is impossible to keep track of tools when they are kept in this way. It should not be necessary for the attendant to take more than a glance at a case to assure himself that a certain tool is in or out; and this is very easily accomplished if a little thought is given to arrangement before fitting up the tool room, though I regret to note that the rule seems to be to get the case built first and arrange them as best you may after they are in place.

Fig. 5 shows a case arranged for twist drills, reamers and milling cutters. The different sizes are arranged in order and in the case of reamers, a slight beading separates one reamer from the other. This case may also be used very conveniently for hand taps and dies, the latter being placed on wooden pins or on a recessed board, similar to those for milling cutters. When tools are arranged in this way there is more inducement for the attendants to keep them clean than where "any old place" is good enough for them.

Ordinary forged tools are conveniently kept in a case with square pigeon holes, the upper portion of the case being arranged for small tools, the central portion for large tools, and the lower portion for mandrels, plug centres and other heavy and bulky tools. Ordinary flat drills are also conveniently kept in such a case. Plug and ring gauges may be neatly arranged in sets either in boxes with hinged covers, or in double slide drawers somewhat after the fashion of those used in vertical letter filing cabinets.

Snap gauges may be placed on one end of a tool case and held in place —the smaller inside the larger—by means of wooden or iron buttons; while drill sockets may be arranged in a similar position in rows—two wooden strips for each row being placed across the end of the case—the upper one being perforated to accommodate the different sized sockets, and the lower one solid to act as a stop.

Other cases will be required, besides those mentioned above, to accommodate tools of a miscellaneous character, which will depend upon the style of work done in the shop; but these can usually be readily decided upon. Special cases will be required for jigs, fixtures, etc., and there should always be arranged where they are easily accessible and not liable to damage.

In many shops oil is served to the men from the store rooms, or they are allowed to help themselves from tank or barrel. In a later article the writer hopes to take up this matter of oil and show how it is possible to affect a large saving by having it served out from the tool room.

In conclusion, I desire to say to those in control of manufacturing establishments: look carefully into the running of your tool room, for on them the officiency of your shop depends more largely than on any other portion of the works.

System of Machine Shop Costs

A description of the system of carrying on production and estimating costs in the plant of the Chapman Double Ball Bearing Co.

By J. C. ARMER.

It is very essential in designing a system for carrying out work in a machine shop, that simplicity be kept prominently in view. The simpler any system is, which at the same time will do efficient work, the better; but it is allowable to have office systems more elaborate than shop systems. The man in the shop who has to carry out the big part of a shop system, is not in a position to do anything very elaborate in this line, and yet the record from the mechanic of work done should be of such form as not to necessitate too much recording work in the superintendent's office.

In present day practice it is not suffcient that only the cost of a machine as a whole be known; but the detail cost of each part should be recorded. With such a record, it is possible to cut down the cost to a minimum. The material used in, and the cost of, each individual part can be investigated fully at any time. Should the cost of production run above the average, the cause can be traced and investigated, by comparing with previous costs.

There is still another feature which

PRO. ORD. NO. | DATE ORD'D | DEPT | ARTICLE | DATE TO BE COMPLETED

DATE COM'CD | PART NO. | DRAWING NO. | FINISHED 0000 DEFECTIVE | DATE COMPLETED

You will please execute the following order, charging all labor and material expended upon it to the above Production Order No. Return this Order to the Office upon the completion of the work.

Fig. 2

should be incorporated in a machine shop system. It should be possible to compare the cost of each individual part of two similiar machines when the two are made in different lots. Thus one might be made in a batch of five while another in a batch of twenty-five. The records should show the advantage to each part in cost of putting through twenty-five instead of five machines, as well as the difference of cost in the two completed machines.

A Simple yet Complete System.

A shop system is used in the plant of the Chapman Double Ball Bearing Co., Toronto, which is both simple and effective. This system was designed and applied by Mr. W. E. Cane, superintendent; and the writer is indebted to Mr. W. J. Murray and to Mr. Cane for the information contained in this article.

The Production Order Form.

When an order comes into the business office, it is recorded, and transferred to the superintendent's office. The superintendent sizes up the order, and makes out production orders for the different parts, with the number of parts required. The production order blanks are on a pad in triplicate, two being thin paper, and the third a heavy card. All three are of different colors. Carbon paper serves for duplicating. The style of this production order is shown in Fig. 1. One of these orders goes to the foreman, another is attached to the requisite blue prints to be handed to the mechanic, and the third, the stiff card, is kept on file in the superintendent's office.

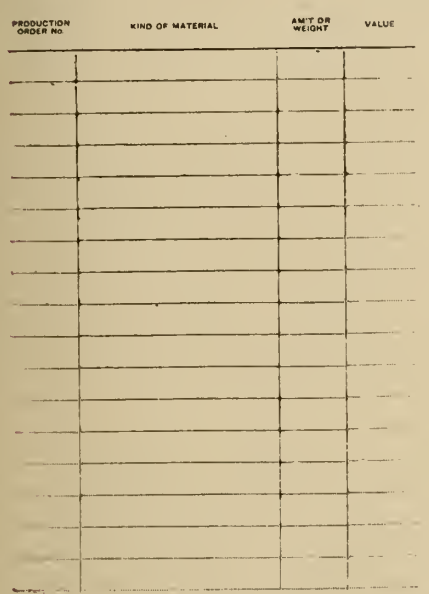

Fig. 3

The details of this production order should be noted. The completeness of the record which can be kept on this card is shown by the heading required to be filled out.

The Shop Time Cards.

Each mechanic in the shop is supplied with shop time cards, as illustrated in Figs. 2 and 3, Fig. 3 being the back of the card. The mechanic receives a production order to carry out, together with the necessary blue prints. This production order will contain orders for one or more pieces of work to be done. The mechanic first secures materials from the stock room, data concerning which is noted on the blue print. He enters the number of the production order on the back of his time card, as in Fig. 3, the kind of the material and the amount. The value is filled in either by himself or someone appointed to do it. He starts work and fills in the blank spaces on the front of his card, such as his number, his rate of wages, the number of the production order, a description of the different operations occasioned by that order, the time taken for each, and the cost of each, computed from the time and his rate of pay.

Cost Data Kept on Back of Production Order Card.

This card, completed, is deposited in the superintendent's office, where data from it can be filled in on the production order card, which was filed in the office (Fig. 1), such as date when completed, good or defective work and signature of approval by the superintendent. The production card is then turned over, which appears as is shown in Fig. 4, and data for this particular production order is filled in from the shop time card, (Figs. 2 and 3.) Thus a complete record of material and labor used in fulfilling any production order is kept on the back side of the production order card. This can be totalled as shown at bottom of card; and the total cost of each article in the order

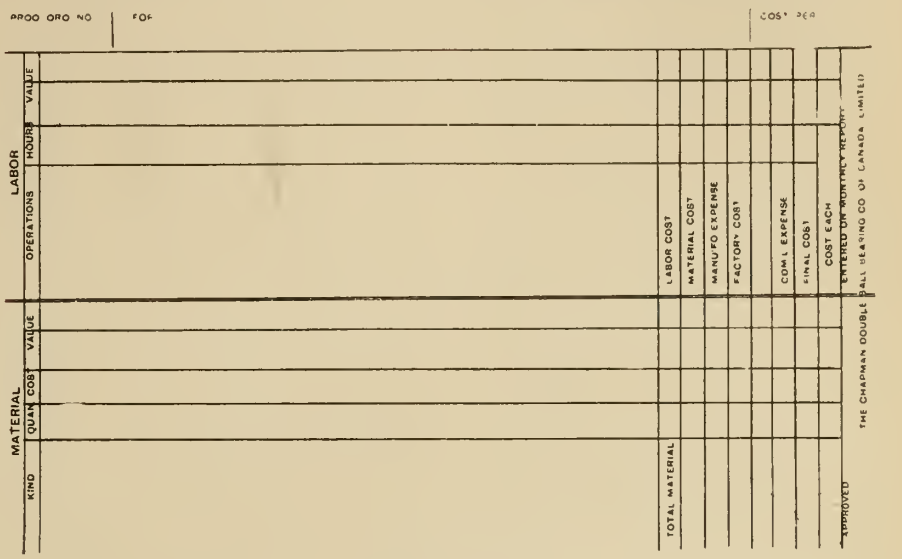

Fig. 4

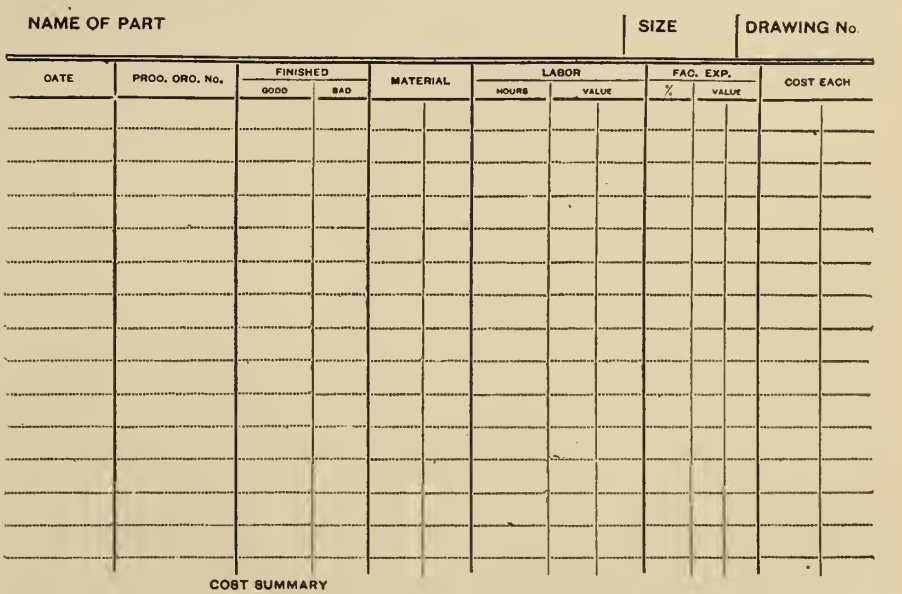

Fig. 5

can be determined by filling in the proper proportion of manufacturing expense, factory cost, commercial expense, etc., which is arrived at through the office system.

One production order may be executed by any number of men, according to the number of operations and the kinds of operations required. They will all work from the same production order, but each will use his own time card. Then entries are made from each time card on the back of the production order card in the office.

Summary of Costs of Individual Parts For Different Orders.

In order to have a concise record of the cost of different parts of a mechanism, there is what is known as a cost summary card, as in Fig. 5. This card is filled out from the back of the production order card (Fig. 4), and also from the front, with name of part, etc., material, labor and cost. A card is kept for each piece. From this summary card the relative cost of any one piece for all different production orders can at once be seen.

—BALLS—

5/16	1/2	5/16	5/8	5/16	1/2	5/16	5/8	5/16	1/2	5/16	5/8

STOCK REPORT FOR WEEK ENDING---------- 19---

Fig. 6

Record of Stock Kept.

There is also a neat system of keeping track of stock in the factory. With this system a complete record of stock is kept on cards, such as in Fig. 6, which are revised weekly. Thus by simply looking over the stock cards, the condition of the stock can be found at a moment's notice. These cards are kept in the stock room, and one for each kind of stock is delivered to the superintendent's office every week. Fig. 6 shows the stock card for balls for the bearings. As these balls are delivered from the stock room, they are entered on the card. This means very little work, yet forms a complete record. Similiar cards are filled out for other items of stock.

All Cards Kept on File.

In the office of the superintendent, all these cards are filed in filing cabinets or on files. The summary cards are kept in a cabinet.

This system has been in operation at the plant of the Chapman Double Ball Bearing Co. since they started operations in their new plant. It has been tested thoroughly and found very satisfactory.

ABOUT CATALOGUES.

CRANES—Circular No. 76 of the Whiting Foundry Co., Harvey, Ill., fully describing, with illustrations, their different makes of cranes and foundry equipment.

TURBINE PUMPS—Bulletin No. 101, issued by the John McDougall Iron Works Co., Montreal, illustrating and describing their electrically driven turbine pumps.

MOLDING MACHINES—Catalogue of the Henry E. Pridmore Co., Chicago, Ill. This catalogue illustrates and describes fully the drop molding machines manufactured by this company.

HOISTING ENGINES—A catalogue issued by Allis-Chalmers-Bullock, Ltd., Montreal, illustrating and describing fully the Lidgerwood hoisting engines, for mining purposes, for which they are sole Canadian agents.

ELECTRICAL EQUIPMENT—Pamphlet issued by the Westinghouse Electric & Manufacturing Co., describing the electrical equipment at the Hornell shops of the Erie Railroad. It consists of 24 pages, 6x9 inches, fully illustrated.

STORAGE BATTERIES—An attractive catalogue of the Westinghouse Machine Co., East Pittsburg, Pa., dealing with their different types of storage batteries. Each type is clearly illustrated, and the catalogue is very neat throughout.

MOLDING MACHINES—A descriptive catalogue, issued by the Arcade Manufacturing Co., Freeport, Ill., illustrating their modern molding machines. The catalogue is well gotten up and includes a number of testimonial letters received by this firm.

GOLDSCHMIDT THERMIT CO. — A handsome catalogue, issued by the Goldschmidt Thermit Co., New York, illustrating and describing the Thermit welding process, together with pamphlet giving full instructions for welding wrought iron and steel rods by the Thermit method.

BLOWERS AND GAS EXHAUSTERS—A catalogue of blowers and gas exhausters, manufactured by the Wilbraham-Green Blower Co., Philadelphia. This catalogue gives the points of merit, and fully describes their blowers and exhausters. It is well illustrated, and is of standard size.

SHIP BUILDING—A neatly bound catalogue of Shaw, Hunter & Wigham Richardson, Ltd., Wallsend shipyard, Wallsend-on-Tyne. This book describes, with fine illustrations, what this firm has done in the shipbuilding line, and also includes a short history of the company, with a detailed list of shipowners for whom vessels have been built. It consists of 40 pages, 6x10 inches, with a strong cover. This is a credit to the firm.

GENERATORS AND MOTORS—A well gotten up catalogue, of the General Electric Co., Westeras, Sweden, entitled, "What We Can Do." This book describes, with half-tone illustrations, the different types of generators and motors manufactured by this reliable firm, and also gives views of a number of power plants, where their motors and generators have been installed. There is shown an illustration of a machine built and installed for the Hamilton Steel & Iron Co.

PERSONAL NOTES.

R. J. Cottrel has been appointed acting locomotive foreman on the G.T.R.

J. H. Mills, formerly road foreman of locomotives on the C.P.R., has been appointed district master mechanic with headquarters at Montreal.

W. H. Towner has been appointed acting general foreman on the Grand Trunk Railway at Toronto shops, vice Mr. J. C. Gerden, resigned.

The headquarters of Mr. S. Phipps, master mechanic of the Pacific Division of the Canadian Pacific Railway, have been changed from Revelstoke to Vancouver, B.C.

A. R. Mackay, formerly an engineer with the Electric Development Co., Niagara Falls, Ont., has this week assumed the position of advertising manager for the Canadian Fairbanks Co., Montreal.

E. E. Austin, formerly road foreman of locomotives on the Canada Pacific Railway, has been appointed district master mechanic of the Pacific Division on the same road with office at Nelson, B.C.

The Control of Superheated Steam*

The Best Materials for the Control of the High Temperatures of Superheated Steam—Iron Castings for Fittings or Valves Unsuitable—Cast Steel and Nickel very Suitable Metals—Best Designs of Valves, Joints, Etc.

By M. W. Kellogg

Since the introduction of superheated steam as a large factor of economy in stationary power plant use, the question of what type of material is best for the proper controlling of the resulting high temperatures has caused a great deal of investigation and interest.

In the following discussion of materials, some reasons will be given which are the results of experience and test, and other facts which we have accumulated from reliable sources will be shown. This article treats particularly of what might be called in a general way, piping systems, which systems are made up of pipe, fittings, valves, and the necessary details connected therewith, such as joints, gaskets, etc, and are taken up separately.

Pipe Considerations for Superheated Steam.

There can be little question as to the matter of pipe except quality. Of course, welded wrought iron or steel pipe is successful, but the difference in the quality of pipe under different conditions is very material. As in nearly all instanecs in a superheated steam station, the old-fashioned serewed joint is not satisfactory, it is necessary to "work" the pipe—that is, weld, van stone, etc. —to make either a welded, van stone, or other joint of the same general description.

The accompanying illustration (fig. 1) is what is known as a "van stone joint."

For this work, the pipe made from open hearth steel is a great deal the best for manufacturing reasons, because it can be properly "worked," there being less carbon, and the quality is much more uniform. Bessemer steel pipe will very often act in a satisfactory manner, but one is never sure that Bessemer will run evenly, and, therefore, troubles may result.

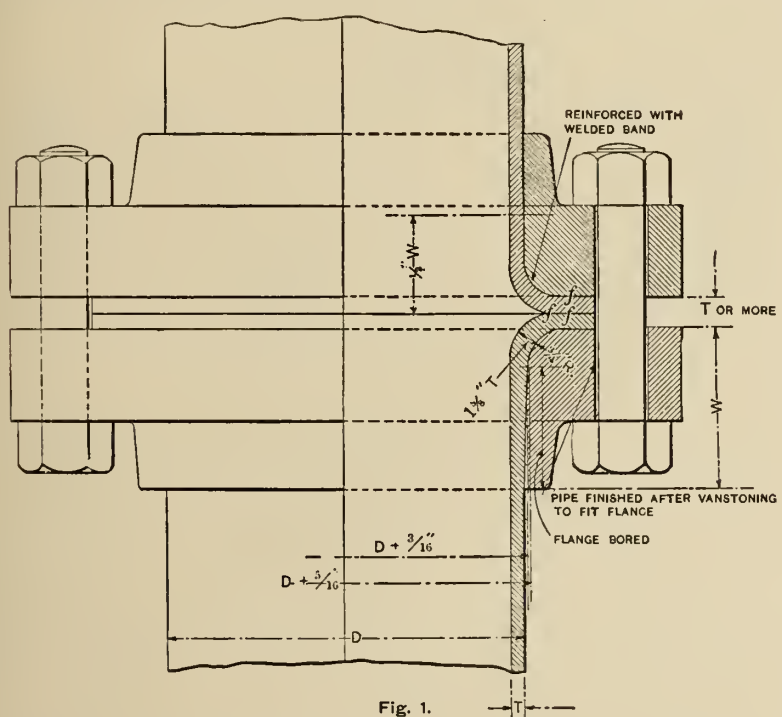

Fig. 1.

It is practically impossible to "work" wrought iron pipe. In making this "van stone joint," the pipe will almost surely split very badly, not only at the weld, but also around its outer circumference.

On the other hand a good quality of wrought iron will cut and thread more easily with standard pipe machines and dies than a steel pipe, and a Bessemer steel pipe will thread much more easily than open hearth steel pipe.

A great many manufacturers have great difficulty in threading open hearth steel pipe, because dies are not set as they should be for open hearth steel. The die in a pipe machine should be set at a greater angle, with the radius of the pipe passing through the point of contact of the die, for soft steel than for other kinds.

Full weight pipe is perfectly suitable for any temperature and working pressure up to 250 pounds, as long as the pipe is not made thin at any point by cutting or threading.

Suitable Fittings.

The general designs of fittings are very satisfactory for use with superheated steam, with the one exception, that very few manufacturers include what is known as the "long fillet" between the body of the fitting and the flange. This is a very desirable point, due to the fact that at this place there is the greatest strain from shrinkage in the molds, which also tends to develop porous spots. Most large users of this type of material have learned this thoroughly and design their fittings specially; the chief difference in their design from that of the general manufacturer merely covering this point. The quality of the material in fittings, however, is a very important thing in connection with superheated steam.

The latest practice is to do away with fittings entirely on high pressure steam lines and put what are known as "nozzles" on the piping itself. This is accomplished by welding wrought steel pipe on the side of another section, so as to accomplish the same result as a fitting. In this way rolled or cast steel flanges and a van stone or welded joint can be used. This method has three distinct advantages, to wit:

(a) The quality of the metal used, for reasons explained hereafter when the subject of the effect of heat on metals is taken up.

(b) The lightening of the entire work.

(c) The doing away with a great many joints.

As a general average, at least 50 per cent. of the joints can be left out, and sometimes this portion runs up as high as 60 or 70 per cent., according to the layout of the system.

If this method is employed, substantial welds must be made, not only to stand the pressures required but also the strains; this is accomplished successfully in Germany, England, and the United States.

* Abstract from a paper presented before the American Society of Mechanical Engineers at the Indianapolis meeting, May, 1907.

Design of Valves.

It is important to have a good design of valve. I believe that nearly any of the designs made by the good manufacturers are entirely suitable; such as a broken or solid wedge valve of the ordinary type, under the condition that all machine work is done thoroughly and the quality of metal used is satisfactory for the purpose intended.

It may be interesting to note here the effect of a large range of temperatures on a short piece of steel. By calculation, a piece of steel six inches long, heated 500 degrees, will expand 0.019 inch. This figure is put down to show how variations in the coefficient of expansion of metals by heat have a large effect on the permanency of a valve staying tight, and it can readily be seen that a small proportion of the distance given is sufficient to cause trouble.

Metals and Temperatures.

I find that different authorities vary slightly in their statement as to what temperatures different metals will stand with good results. German authorities state that cast iron should not be used above 480 degree F. Other authorities allow us to go as high as 575 degrees F. Above these temperatures in cast iron the limit of elasticity is reached with a pressure varying from 140 to 175 pounds. Under such conditions the material is strained and does not resume its former shape, and eventually shows surface cracks, which continue to grow until it lets go. These temperatures and pressures also lead in time to a shrinkage of all parts, and to a structural alteration of the metal which results in leakages in valves at the seatings. Therefore, it would seem that iron castings are unsuitable for both fittings and valves to be used in any superheated steam work. While they may last for some time, after a few years' use the metal becomes very weak and some cast iron has reached the point in weakness where if it were merely tapped lightly with a hammer it would break into pieces.

The only adaptable metal I believe to be cast steel. The results of tests by Bach on this metal for the effect of temperature are such that at 572 degrees F., the reduction in breaking strength only amounts to about 1.1 per cent. and at 752 degrees F. to about 7.8 per cent. Therefore, it seems that this metal is practically capable of withstanding all pressures and temperatures up to at least 800 degrees F., without showing any appreciable weakness.

The influence of high temperatures on bronze, etc., is very material. At ordinary temperatures this metal has a breaking strength of about 34,100 pounds per square inch and an elongation of 36 per cent. At 572 degrees F. the breaking strength falls to about 19,500 pounds per square inch and the elongation to 11.5 per cent. At 662 degrees F., which is quite a common temperature, as it leaves the superheaters, the breaking strength of bronze only amounts to 12,200 pounds per square inch and the elongation at the breaking point is only approximately 1¾ per cent. This seems to eliminate entirely brass or bronze of ordinary composition for use with highly superheated steam.

The effect of temperature on nickel is very similar to that of cast steel and in consequence this material is very suitable for use in connection with highly superheated steam. Bach recommends that bronze alloys be done away with for use on steam lines above temperature of about 390 degrees F. Even neglecting the special quality of nickel seatings, on account of the great toughness of this metal and the methods which can be used for securing rings of this substance to the valves and conical surfaces, it has the special advantage of having the coefficient of contraction and expansion with temperature almost exactly the same as that of cast steel, so that no slackness of the rings occurs and the valves remain absolutely steam tight. There are instances in which valves constructed with nickel seatings have been satisfactorily used with steam temperatures up as high as 932 degrees F.

Seats, discs, and bushings made of brass or plain bronze do not retain their shape.

For spindles on superheated steam work I strongly recommend nickel steel, which holds its shape and does not deteriorate with high temperatures.

Seatings in valves should not only be screwed in but also pinned in addition, using a fine thread which is very long, to give a tight joint. Seats should also have a flange on the top that makes a joint with the body when screwed down, which prevents the tendency to leak through.

I think it is generally acknowledged that the old fashioned screwed joint, no matter how well made, would not be suitable for superheated steam work. This leaves for discussion two general types, viz.: welded joints, and what are generally known as van stone or climax joints; that is, any joint where the pipe is turned over the face of the flanges.

In welding a flange on a piece of pipe, great care must be taken to see that the weld is perfect because of the unequal thicknesses of the metals to be so welded. If the weld is thoroughly made, this type of joint is very good, although for erection purposes, due to the fact that the flanges cannot swivel, it does not equal the turned-over joint as mentioned above. The manufacturing expenses in making a welded joint is very good, although for erection purposes, due to the fact that the flanges cannot swivel, it does not equal the turned-over joint as mentioned above. The manufacturing expenses in making a welded joint are also much more for the same type of work accomplished, on account of the necessity of doing all finishing work after all rough work, such as welding and bending, has been completed. Therefore, the cost of welded joints is greater, not only for the work done but because of the increased expense in finishing on account of the necessity of employing methods different from those where the flanges, etc., were all finished before the joints were made, as is possible on the turned-over joint mentioned above.

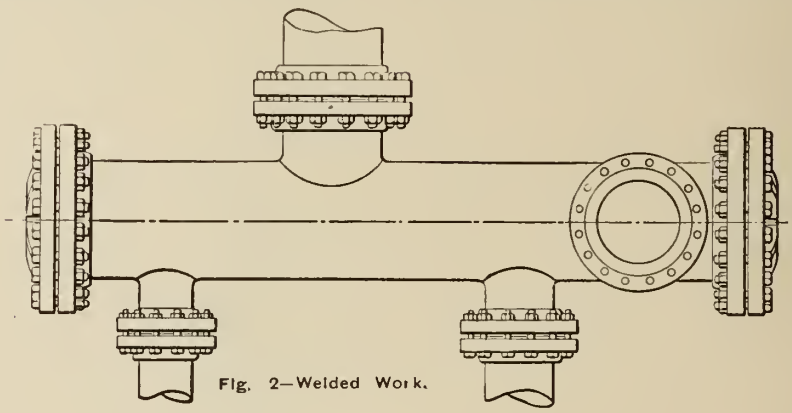

Fig. 2—Welded Work.

In regard to the turned-over or van stone joint, the quality of its manufacture seems to us the most important feature. This joint can be made in a careless way where the pipe is in no way thickened up and only faced on the front. A joint of this kind does not give good results, principally for two reasons:

(a) The thinness of the metal on the turned over portion; and

(b) On account of the recesses left between the back of the pipe on the turned over portion and the flange, due to the pipe not being finished at this point.

The writer believes, however, if this

joint is properly made, it is equal to the welded joint as a manufactured article and superior to the welded joint as an article for erection.

To have this type well made, the pipe on the end should be thickened up in an amount sufficient so that after the joint is turned over there will be enough metal left to face the turned over portion on the front, on the outer edge, and on the back. We of course take for granted that the flanges are finished on the front. After the work above mentioned is done, the pipe should be as thick on the turned over portion as the original thickness, or very close to it. Increasing the thickness of the pipe on the end before going through the operation is done in several ways. In a general way, I consider any of the methods satisfactory. The point made of facing the turned over portion of the pipe on the back is an exceedingly important one, much more so than most people seem to realize. I have known instances where it has been found impossible to make a ground joint, for no other reason.

In reference to making up a joint, I believe that the face of all flanges or pipe where a joint should be made ought to be given a fine tool finish and have the face level, and then use a gasket of some description. A perfectly made ground joint is a good thing but it is very expensive, and it is hard to get the average contractor to furnish it in a perfectly workmanlike manner. Also, after it is so done, it is liable not to stay tight, on account of the tremendous expansion and contraction causing such strains that the joints are liable to open up, particularly when the pressure is taken off the plant. The simple expansion and contraction on the bolts that make up a joint would cause this.

Gaskets for High Temperatures.

There are large numbers of gaskets manufactured of all types and descriptions. It is very hard to take up this subject and be fair to each of the manufacturers, for the reason that practically no one can and has had experience with every type made to judge for himself, and hearsay would lead us to suppose that all of them are at one time perfect and at other times useless.

I have used a great many different types of gaskets, however, and have obtained the best results with a corrugated soft Swedish steel gasket with "Smooth-on" applied, and with the McKim gasket, which is of copper or bronze surrounding asbestos. The ordinary corrugated copper gasket is a very popular make and has been used a great deal. On superheated steam, usually sad results follow. There seems to be some peculiar action that causes this, as on superheated steam lines a corrugated copper gasket will in time pit out in some part of the flange nearly through the entire gasket. I have heard a great many reasons given for the cause, such as electrical action, disintegration, etc.

The wear of a gasket depends largely on the method of pulling up bolts on flanges. In fact I believe that a great many troubles have occurred because of imperfect erection. If joints are pulled up entirely on one side and left loose on the other, and then taken up on that side, trouble with the gasket is almost certain. The bolts should be taken up gradually all around the flange. The experience of the erecting crews on high class superheated steam lines is an exceedingly important thing. The average steamfitter is not suited to this type of work. He has had experience with lower pressures and less important tasks and after a piece of work is erected by him it is customary to find a great many leaks which are usually only eradicated after the whole joint has been broken and properly repaired. All these troubles can be eliminated by using only steamfitters experienced in the type of work under consideration.

Discussion of Paper at Convention.

There was some discussion on this paper at the convention, and Mr. Foster did not agree with the author in regard to the difference between pipe lines carrying superheated and saturated steam.

A pipe line carrying a moderate superheat, say up to 500 degrees Fahr. would not differ materially from one carrying 150 pounds saturated steam. Mr. Foster did not agree with Mr. Kellogg's conclusions in respect to gaskets, nor to the use of east iron, rather favoring east iron.

J. Roland Brown commended the use of van stone joints, but advocated at least one threaded and flanged joint in the line for convenience of make-up in the field. More pipe lines are injured by springing in the field because they do not agree with the drawings than by any other cause. The method of installing gaskets has more to do with their success than the style of gasket. Mr. Brown spoke of three successful types of gaskets, a long five asbestos gasket held with a small quantity of binder and coated with graphite; a joint made by grinding together a male and female flange and inserting a soft steel corrugated gasket covered with graphite and oil; and two flanges with a groove into which a cast iron ring is inserted. This last type is especially good on heavy fittings.

A paper was presented by R. P. Bolton on the above subject. His paper criticizes the existing practice of applying superheaters to boilers and states that by merely placing a superheater coil in a certain part of a gas passage of a boiler and connecting a steam supply to it is by no means to be regarded as a complete solution of the problem. The operation of an ordinary boiler, furnace is subjected to so many variable elements in the nature of the fuel, its combustion, draft regulations, door openings, ash and clinker accumulations and the personal equation that an apparatus as sensitive as a superheater should be protected from these varying influences. The disappointments experienced in superheated steam operations of high temperature are due to these influences and fluctuations in the steam output of the boiler, which will also affect the degree of superheat. Furnace conditions should be such as to eliminate all fluctuations in the flow and temperature of gases, or the heater must be placed so that the flow of the gas volume can be controlled.

In regard to this paper, J. R. Brown stated that where the superheater is located where it is not exposed to more than 1,000 degrees Fahr. it is unnecessary to flood the superheater when raising steam if fair judgment is used. When a superheater of the boiler setting type goes out of commission, it will cause the loss of only one unit and the ratio of superheating to water heating surface in the rest of the plant remains the same. When an independently-fired superheater goes out, it reduces all or a large part of the plant to saturated steam conditions. In large units, the boiler setting type of superheater, as now designed, does not average over 175 degrees superheat, although some are sold to develop 200 degrees. In order to get the higher degree of superheat, it is necessary to increase the height of the boiler setting.

BOILER MANUFACTURER DEAD.

Arthur G. Booth, secretary-treasurer of the Booth Copper Co., Toronto, died recently.

Mr. Booth was but thirty-eight years of age, and had been ailing for about a year.

Besides his wife and children, his father, Geo. Booth, president of the Booth Copper Co., and two brothers, Walter C. and Clarence H. Booth, survive him; the former is vice-president of the above company and the latter head of the Pressed Steel Bath Co., Detroit, Mich. The late Mr. Booth has had a long and successful business career and was at one time secretary of the Steel Clad Bath Co., Toronto.

Success depends as much upon the use of our off working time as it does upon our hours of labor.

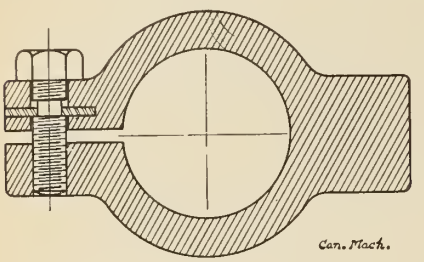
WAYS AND MEANS OF DOING THINGS

FOR BORING ARMATURE BEARINGS.

This is a chuck used to great advantage by the Toronto Street Railway Company for boring out babbited armature bearings. The chuck is of ordinary design, but has one unique feature—that instead of being bored out 1-32 in. larger to admit of insertion of bearing and then being clamped down, as is customary, it is bored to exact diameter of bearing, and by means of a slot cut as shown at A, and a piece of bent plate inserted, against which the shoulder on the clamping screw acts, when screw is backed out, the chuck will open sufficiently and quickly to allow of bearing to be extracted. It is especially useful where a great number of bearings of the same diameter have to be bored and it can be seen that the bearings will always be bored on the dead centre. The lug on the opposite side is put on simply to balance the chuck in the lathe, and can also be used when the thread in the other lug becomes stripped, or otherwise useless.

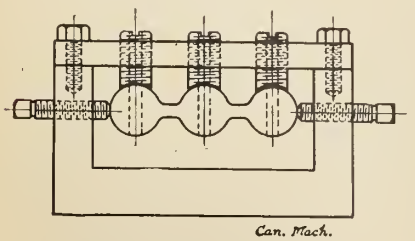


Boring Armature Bearings.

JIG FOR DRILLING LATHE HANDLE

By A. Allen.

Herewith is presented a jig for drilling a three-ball handle for a lathe, and the jig can be modified to be of value in drilling similar pieces.



Jig for Drilling Lathe Handles.

It consists of a cast iron base to which is fastened a cast iron plate by means of cap screws. In this plate are tapped three steel bushes whose inner diameter is the same as the diameter of the hole to be drilled. The drill is guided by these bushes and, as can be seen, the holes will be strictly parallel and at correct centres, as centres are always fixed beforehand. The handle, as seen, is held in position by set screws. It has been used to great advantage in the shop of John Bertram & Sons, Dundas, Ont., and also in that of the Toronto Gas and Gasoline Engine Co.

BRUSH HOLDER ADJUSTING RIG.

By H. Hutchinson.

The accompanying illustration is of a jig used in the machine shop of the Toronto Railway Company as a brush holder adjusting rig.

The jig consists of a metal bedplate to which is bolted a cylinder the same size in diameter as the average commutator. In the centre of this cylinder is a post about 4 inches in diameter. The cylinder is slotted to receive a steel insert the same size as a carbon brush, and the post is also slotted to allow the steel insert to enter. An adjustable bracket is also bolted to the bedplate to permit of regulating the distance between the centres of the different types of motors. The complete brush holder is then bolted to this bracket and, if correct, the steel insert will easily pass through carbon-holder, cylinder and pocket in the slot in the centre part of the jig. By these means proper distances and angles are secured.

LEARN TO ESTIMATE.

By L. Marteaux.

To make a correct estimate is not easy, and it takes a good deal of experience. There is a great difference between an estimate and a guess.

However, there is to my knowledge not much difficulty in fixing the price

of tools which are made for shop use only. The cost of such tools is a secondary matter, as the profit is to come from their product. An estimate is of more importance where the tools are sold, and where the competition of others in the same line of business has to be met.

In answer to an advertisement of ours a diemaker applied for work; in asking him the usual questions, he told me that he had been in business for himself, but had given it up. He was put to work and proved to be a good mechanic.

He had finished a die and, when I was inspecting it, he asked: "Do you mind telling me how much this die is worth?" To which I answered: "How much do you think?" He pondered a little and then he said: "Is it ten dollars?" I could not help laughing. His time on the job amounted to $13.55; material and blacksmith, $4.80; total $18.35, not including shop expenses or profit. I could not help telling him that he had probably done better for his customers than for himself.

This shows that a man may be a good mechanic and still not be able to know it, also their rate of wages, as in accompanying table:

Order No. 80643.	Article.	Price.	To Whom it Was Sold.
Name of Workmen.	**Hours.**		
C. B.	10–10–10–10	= 40 at 30 cents.....	$12.00
P. D.	3– 6–10– 6	= 25 at 27 cents.....	4.75
T. G.	5–10–10– 3	= 28 at 20 cents.....	5.60
M. L.	6–10– 4– 3	= 23 at 20 cents.....	4.60
			$26.95
Blacksmith			4.00
Material			8.25
Total			$39.10

This may seem a laborious job, but it is easy. It takes only a few minutes every morning and it is well worth doing. After the job is finished I can tell in a minute the result. I can tell by it if my judgment in the ability of my men is correct. The results have been in most cases satisfactory, excepting where things happened which were beyond control. I have continued the use of the memorandum books, and they have accumulated to 14 in number. They contain a lot of information as to prices, methods of doing certain work, and mistakes. Yes, I have recorded my mistakes, too.

In the course of years I have gained a lot of experience in estimating and otherwise, but (I will not say I am entirely fool-proof) of this fact I am reminded when I look at my memorandums, from every page I can see that time and patience are required to get experience, and that this experience cannot be bought at so much per pound.—American Machinist.

the value of his work, which is the first requirement for estimating.

Quite a number of men don't think it worth while to figure up how much time they put on a job. They don't seem to think that some day they might be asked to estimate. I believe that every man should have a note-book in which to keep the time spent on each job, and in doing so he will be able to judge intelligently the value of the work he has done.

When making my first estimate, I figured how many hours it would take me to do the job myself. Being only a few days in the shop, I had had no chance to find out what my help could do. But I was determined to find this out, so I decided to make my quotations in duplicate for some time to come.

To compare the result obtained with my quotation, I entered every order on another memorandum, noting the price quoted, the time for doing the work, and the name of the man or men doing

JIG FOR FINISHING ECCENTRICS AT ONE SETTING.

By W. C. Murphy.

Anybody who has had anything to do with finishing eccentrics has undoubtedly run up against the difficulties in such jobs. As I have some time been doing this work on an improved turret lathe, I have myself realized some of the difficulties attached to this job. Recently our general foreman devised a simple jig for boring and turning locomotive eccentrics at one setting.

It consists of two plates, the main plate as shown in Fig. 1 and the sliding plate as shown in Fig. 2.

The main plate is secured to the machine by means of the boss on the back fitting into the hole in the chuck (the jaws having been removed) with three cap screws C C C through the plate into the chuck. The centre slot is to fit a like tongue on the sliding plate. The short slots on either side are to receive the four bolts (x x) which hold the sliding plate to the main plate and are made long enough to allow a shifting of the sliding plate equal to one-half the throw of the eccentrics to be machined. The oblong hole in the centre of the sliding plate is made wide enough to clear the boring bar and long enough to permit the sliding of the plate equal to one-half the throw of the eccentric. Holes D D shown in Fig. 2 are stop-

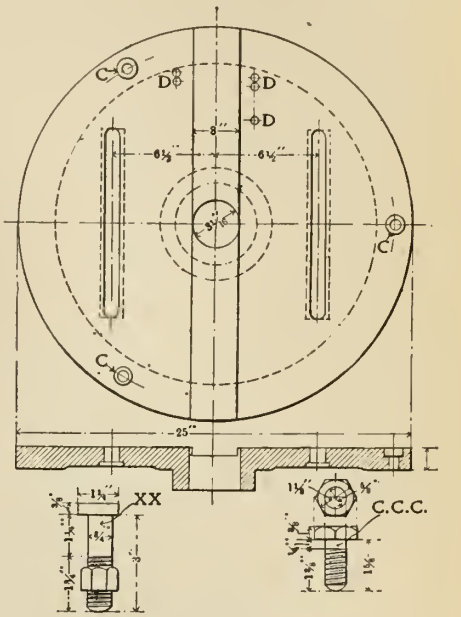

FIG. 1. MAIN PLATE DETAILS

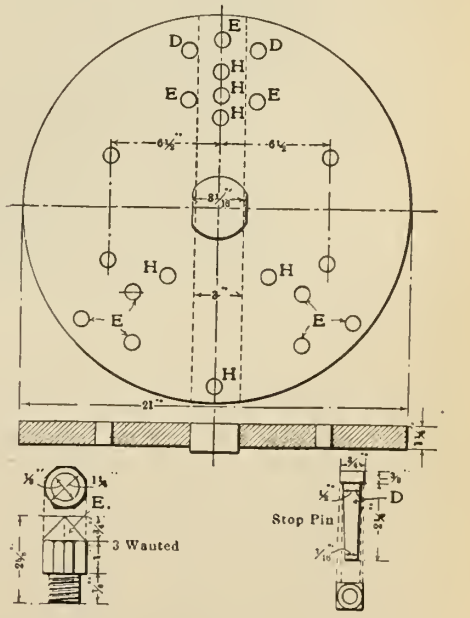

FIG. 2. SLIDING PLATE DETAILS

Jig for Finishing Eccentrics.

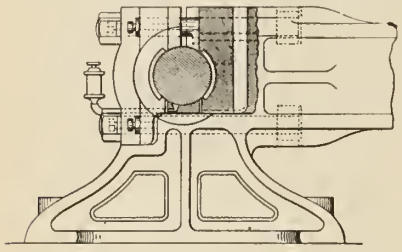
pin holes which match up with holes D D in the plate, Fig. 1. These holes are located at distances from each other equal to one-half the throw of the eccentrics. The holes E E, etc., are to receive centres E and are located in such a manner as to strike the solid part of the eccentric. Holes H are for studs

used to clamp the work to the face plate in the usual manner.—American Machinist.

OILING BEARINGS.

By E. S. Newton.

I am prompted to give a bit of my experience along this line. Some 20 to 22 years ago we made an engine to run an electric light plant, with cylinder 24x48 inches, which was a pretty large one for our small shop to tackle. Soon after it was running, it developed an inordinate desire to heat the main bearing. This bearing was 12 inches in diameter by 21 inches long; the quarter boxes were babbited, and the bottom shoe was of phosphor bronze 8 inches wide, giving 168 square inches to carry about 18,000 pounds, which would not seem excessive, only a little over 100 pounds to the square inch. The box was equipped with two sight feed oil cups, and had an opening on top 6x16 inches down to the shaft. The first regular run it made was only a few hours long—a "moonlight run"—and the engineer managed to keep it going. Soon the runs lengthened, and then the trouble grew serious. One morning after an all-night



Oiling Bearings.

run I went over to the plant and it seemed as though there was a barrel of tallow on the floor—tallow mixed with black lead, oil and water (only the water didn't mix), and the box was then too hot to handle. Something had to be done and as I was practically responsible for the outfit, I felt a trifle worried. I don't know as it does any good to look at a thing that "acts up" but I did look at it a few minutes and then asked the engineer to take off the cap and take out the bronze shoe and send it to the shop.

I cut a groove 20½ inches long as near the edge of the shoe as was practicable and put in the pipe and sight feed oil cup, shown in the cut. We got it back in time for that evening's run, and from that time till the engine was replaced by a larger one, some four or five years later, that bearing was never any warmer than the air in the room. As first made, this bronze shoe was beveled to carry oil under the shaft, and grooved diagonally according to the time-honored custom. We noticed one curious thing about it; if the oil cups on top were set to feeding, oil would run out over the top of the added oil cup at the left, just as much as was delivered by the two on top; stopping the oil from the top resulted in the new oil cup instantly becoming operative again. The engine ran "over;" had it run "under," I would have cut the groove at the other edge, and carried oil to it by drilling all way through the shoe.—Machinery, N.Y.

A STORY OF EDUCATION.

By W. D. Forbes.

A young man came into a machine shop and got a job as lathe hand. He was good at his work and ran his lathe at proper speeds on various diameters when the material was considered, and he took big cuts and fine ones in their proper places, earning his sixteen dollars a week.

On Saturday nights he with many of his shopmates took in a vaudeville show and contentment, to a very large degree, was his lot. Every now and then he had to cut threads and he would look at a little brass plate on the headstock of his lathe and it would tell him what gears he had to put on the stud and on the screw, and there was no trouble at all in getting the right thread.

He often heard about the "angles of threads," their "pitch," "the area" of a piston and the "tensile strength" of steel and iron and other metals, of "plans" and "elevation," but just what they all meant was not clear to him.

One day the foreman gave him a job which required 11½ threads to the inch and his little plate failed him. He told the foreman that his lathe would not cut 11½ threads. The foreman asked why it would not? He did not know. He thought he remembered that a lathe he had seen did cut 11½ threads.

The foreman looked at the little plate, figured a half minute and told him to use certain gears and to his great surprise the job came out all right, and to him the foreman became a great mathematician.

Some time later again the little plate failed and the foreman was out looking after a break-down job. Here was real trouble. The work was wanted at once and he could not do it. An apprentice boy who had helped him now and then in taking off his chuck and putting long pieces between centres, asked what was the trouble and was told. In a few minutes the proper gears had been figured out by the apprentice and with fear and trembling used, and "mortification" set in when the job came out all right.

A few nights later the lathe hand was at an evening school with the apprentice awkwardly working over a drawing board. In six months he had mastered the mysteries of "plans" and "elevation" and "assembled drawings" and what had been so hard before to understand in blue prints was now clear, and the words "angles" and "areas" conveyed real meaning to him. He could figure out just how many feet the surface of a shaft was making in a minute and what size piston rod should be used for a given area of piston with a given steam pressure, and he could cut any thread wanted without ever looking at the little brass plate.

He was so carried away by the desire for knowledge that he began to feel very sorry for the rest af his fellow workmen and he induced many to go to night school.

One day he asked the foreman for a raise in wages and got it the next week. This acted like a spur to a horse and the value of education and knowledge was practically proved. He talked education at noon to his shopmates and before he knew it he was shouting its value like a campaign orator. He besought all to study, learn, and thereby rise to higher planes so that they could all become foremen and proprietors.

Soon he was made foreman of a room, he never went to vaudeville shows but took in all educational lectures and he continued to extol the value of education. He did not, however, find being a foreman as easy a job as he thought it was and he began to understand why a foreman was so anxious to get the work out quickly and swore so when a job was spoiled or delayed.

One thing troubled him, however, a good deal and that was the fact of not being any happier than he was before he gained knowledge—the ability to figure out threads and areas, and to know what π stood for. To be able to figure threads and almost everything else was nice but he worried because he could not tell the difference between an involute and an epicycloidal form of tooth and more because so many jobs were spoiled by the men and that was something he never did before he was a foreman.

He still talked education to his men. One day while doing so at noon he pointed out of the window to two men digging a ditch in the street and said "Knowledge is what you want. Look at those two men at work in the street at a dollar and a half a day. With knowledge they could lift themselves above such work and earn twice as much!" Mike, the oiler, who sat by his side smoking his clay pipe, looked up and said, "If we all got education who would dig the ditches?"—American Machinist.

Developments in Machinery

Metal Working Wood Working **Power and Transmission**

NEW QUICK CHANGE MILLING MACHINE.

The Adams Company, Dubnque, Iowa, are placing upon the market the Farewell quick change milling machine that embodies several features not found in machines in this class.

While it is a hand or lever fed machine, it is intended not only to do the light work usually done on hand-fed machines, but to do accurately and more quickly much of the work usually done on a shaper, on larger and more expensive power-fed milling machines, on the profiler and on the cam cutting machines.

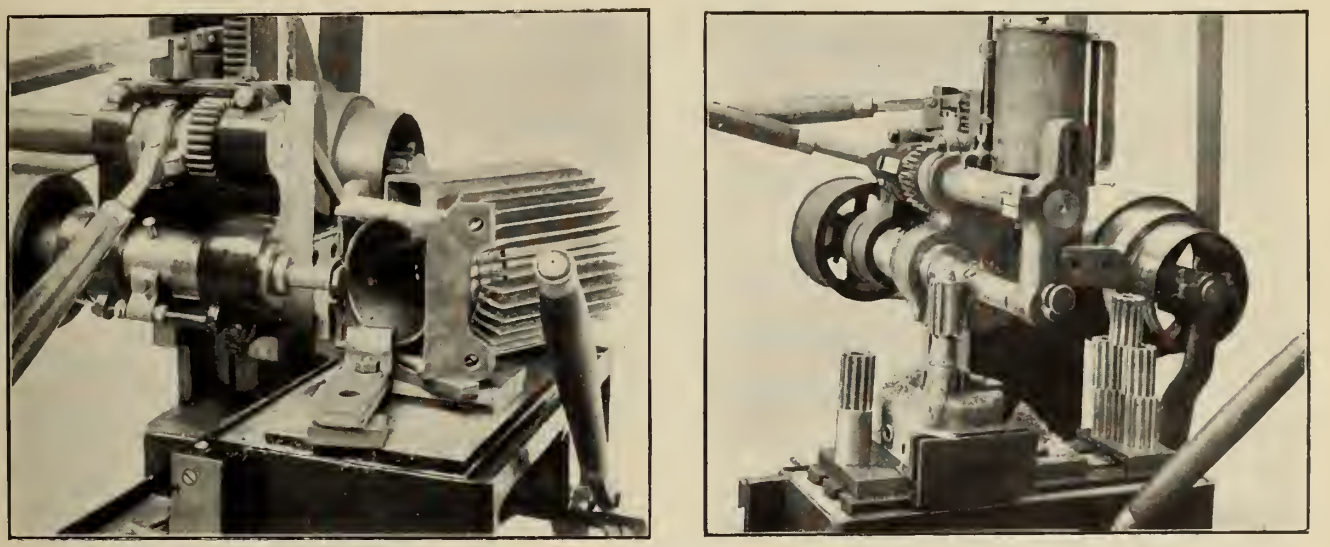
The table has an inclined bearing surface of 1½x23½ inches, running the entire length of the table and two vertical surfaces 1½x23½ inches, also the entire length of the table. This feature is claimed to be conducive to the least lateral lost motion and liability to chatter that it is possible to secure in a freely moving slide. The weight of the table and all upon it tend to hold the sliding surfaces in constant contact. The table has a finished or working surface of 8x18 inches, unusually wide to accommodate bulky work and to give wide transverse range of adjustment to chucks and vises.

buckle holds the swinging cone pulley shaft in position to keep the spindle belt taut in all positions of the head.

Six spindle speeds are obtainable. The spindle is of forged crucible steel and is hollow its entire length. The spindle bearings are bronze and are tapering. Provision is made for a quick and sensitive adjustment of the spindle bearings in the quill.

The pendant is provided with a centre controlled by thumb screw to steady long arbors. Can cutting guide pin may be secured in the other end of pendant.

The vise furnished with the machine has jaws 6 inches wide, 2 inches deep



Two Views of New Quick Change Milling Machine.

With carbon steel cutters, when the tooth contact was comparatively slow, power feeds were required to get the slow, steady feeds necessary to produce true, smooth surfaces; but with high speed steel milling cutters, with the tooth contact nearly quadrupled, the surface produced by hand-fed mechanism is satisfactory and the rapidity of operation, particularly on short cuts, greatly increased.

Instead of following the common practice of providing the vertical and transverse adjustments in this milling machine, by interposing double or treble sliding elements between the work table and the column of the milling machine, which makes rigidity of the table impossible, the table of the Farwell quick change milling machine hangs and slides upon a vertical rail. There is but one slide between the table and the column.

The spindle head is counterbalanced by weights in the column. Part of these weights, like scale weights, may be removed so the weight of the head will feed the cutter down into the work by gravity, or additional weights may be added so the cutter will feed up, the weights being heavier than the head. The vertical movement of 12 inches is provided.

As both the vertical and transverse feed of the cutter is independent of the table, or the weight of the work upon the table, small cutters may be sensitively fed both in and down, without danger of breaking cutters.

The drive of the spindle is by a 4-inch belt from the swinging cone pulley shaft and by a 2½-inch belt from the cone on swinging shaft to the countershaft.

A distance rod with adjusting turn

and opens 3 inches without reversing. By reversing the sliding jaw the vise will hold work 6 inches wide. The vise is exceedingly heavy and is provided with engaging flanges so it may be secured in the quick change clamps in two vertical, as well as two horizontal positions.

The three-jawed chuck furnished with the machine is 6 inches diameter, has two sets of jaws and will take 1 9-16 inches through the centre. The chuck is mounted on a heavy angle plate which may be secured by the quick change clamps in two vertical and in a horizontal position. The chuck has 24 stops or gradnations which are very convenient in spacing cutters, laying out key ways on quarters or opposite sides of a shaft, or for squaring or milling hexagon heads. This chuck is also very convenient for circular miling.

The quick change features, whereby

the positioning of the cutter in relation to the work, the quick locking or releasing of the various slides, the quick change of the position of the feed levers and the quick change clamps for the vises, chucks and fixtures are peculiarities of this machine.

Quick Change Features.

The feed levers not only move the table, spindle or head slides, but also locks these slides by a right angle movement of the lever. This is of great convenience in profiling or when feeding in two directions. By this arrangement the table may be locked, the cutter fed into the work to proper depth, then locked and then the table released and the longitudinal feed begun, all without the use of wrenches or without the operator removing his hand from either of the levers.

The lever, when moved to the locking position is disengaged from the pinion it controls, so the lever may be swung to a new position. The act of unlocking the slide re-engages the lever and the pinion in the new position.

Profiling and Cam Cutting.

The spindle head is provided with an arm extending back and in line with the spindle in which a guide pin may be secured either 4, 6, 8 or 10 inches from the spindle centre. A guide pin may also be secured in the overhanging arm pendant either 2½ inches or 3½ inches from spindle centre.

A roller the size of the cutter on either of these guide pins will follow a pattern secured to the table, chuck or angle plate, while the cutter will duplicate the form on the work. The power of the spindle drive and the rigidity of this machine permits of heavier cuts with larger cutters than are usually used on profiling machines.

IMPROVED BATH GRINDER.

Improvements which have been made in the bath grinder have greatly increased the efficiency of the machine. The accompanying illustrations show the new machine. It will be noticed that a marked improvement has been made in the spindle head over the old pattern. The head is much heavier and is bored tapering to receive split boxes. The large ends of the taper boxes are at the ends of the head, giving rigidity to the spindle at both ends, upon which the wheels are mounted. Surrounding the spindle box on the right-hand end of the spindle head is a projecting square flange, to which the wheel hood is clamped. This flange is independent of the box bearing. It will be noticed in clamping the hood to the head that the clamp screw for binding same is in a straight line under the spindle, making a rigid safety clamp in case the wheel breaks.

Fig. 1 shows our extension arbor support, for surface grinding. On the top of the front face of the spindle head is ¾-inch slot for locating the support. The arm has a tongue on the back side which fits into the groove on the spindle head and is clamped to same by two screws. On the projecting end of the arm will be noticed a phosphur bronze bearing, the lower end of which is adjustable to the spindle. This assures absolute rigidity and allows no spring in the spindle when doing surface work. Mounted on the end of the arm is a wheel hood arranged for holding the water spout. In this case, the water spout is used on either wheel hood as shown.

The spindle head is elevated by the vertical handwheel on the top of the machine. A graduated dial reads the vertical movement to .001 inch, reading the clearance when grinding cutters. The head spindle is driven by a horizontal belt and any tension of belt desired is obtained by the adjustment of nuts, shown on the rod on each side of the cone frame.

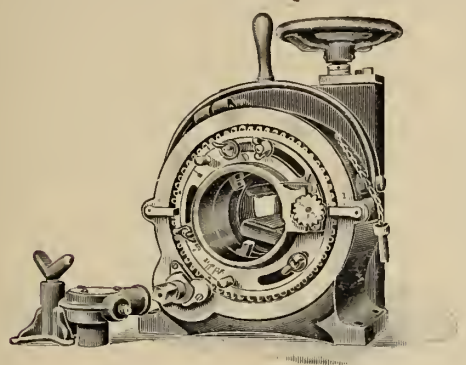
Another improvement is the lengthening of the bearings of the table slide, this adds greatly to the rigidity of the machine. On the left hand side of the apron, opposite the two handwheels, is shown one of the combined levers for reversing the machine in either direction or locking the carriage at any desired position. By this construction, in all kinds of grinding, it requires only

Fig. 1—Improved Bath Grinder.

Fig. 2—Improved Bath Grinder.

one hand of the operator to reverse or stop the machine, leaving the other hand free to adjust the work, as in cutter grinding. This is a most desirable feature on grinding machines.

Capacity of machine as follows: from

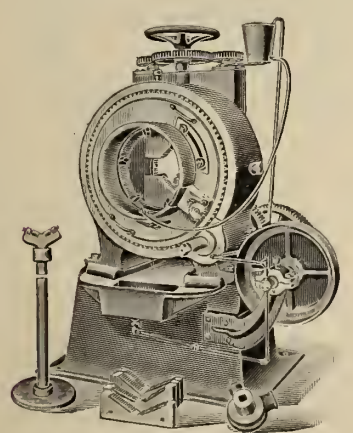


Forbes Patent Die Stock.

centre of spindle to top of swivel plate, takes 36 inches between centres and will swing 9½ inches or 14 inches. Will surface grind 36 inches by 8 inches. Machine complete with all attachments weighs 3,500 pounds. These machines are made by the Bath Grinder Co., Fitchburg, Mass.

FORBES PATENT DIE STOCK.

All who have had experience in the cutting and threading of wrought iron pipe, and especially the larger sizes, know well the difficulty with which it is attended. Either a hand die stock with its long handles, or a cumbersome, heavy and expensive machine must be used; in the former case it is rarely that anything larger than 4-inch pipe is attempted, and even then requires four men to do the work, and very hard work it is; in the latter case, the machine is not portable and all the pipe has to be carted to the machine, and as they take up so much room and are so very heavy, it is unpractieable to use in confined places or in isolated mills.



Forbes Patent Die Stock.

Herewith is illustrated the Forbes Patent Die Stock, manufactured by The Curtis & Curtis Co., of Bridgeport, Conn., which it is claimed meets the requirements of the case without the above disadvantages. The machine consists of a die carrying gear supported and surrounded by a shell and actuated by a small pinion embedded in the side of the shell and working on the large gear with the pipe vise attached to the back of the machine. To operate it, the pipe is placed through the pipe vise with the end to be threaded against the back of the dies. The die carrying gear is then revolved by means of a crank on the end of the pinion; as the dies revolve, the gear is drawn back into the shell and the dies are thus brought on to the pipe. These dies are opening and adjustable to any variations of fittings and when the thread is cut, they can be opened and the pipe taken out without running back or stopping the machine. In cutting off pipe the gear is shoved back in the shell and held by a stop so as to give it a rotary without a traveling motion. A blade cutter is then inserted in the gear which is automatically feed forward as the gear revolves.

These machines are made in a great variety of sizes, to meet almost any range desired, from ¼ I.D. to 15 O.D. for hand or power. All hand machines can be made into power machines by the addition of a cast iron base, with the necessary gearing and countershafting, therefore, they can be run as power machine in a shop, or taken from the base aud used on outside work as a hand machine.

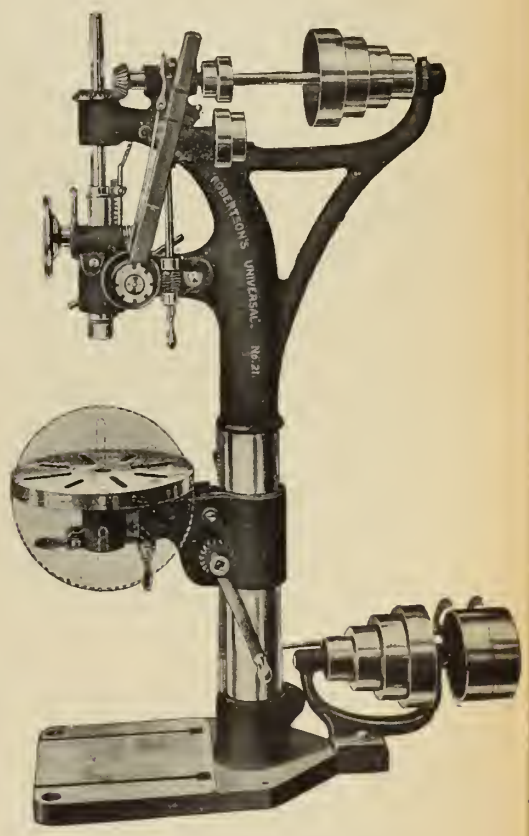
When desired, a direct connected engine or motor is connected with them, so that they can be run directly from a steam or electric current, without the necessity of having power available.

ROBERTSON UNIVERSAL DRILL PRESS.

One of the important features of the drill press manufactured by the Robertson Manufacturing Co., Buffalo, N.Y., is the universal adjustment given to the drill table. As may be seen in the cut, the table can be rotated about a horizontal axis, thus making it possible to drill a hole at any angle with the surface by which the work is fastened down. The value of this feature has been demonstrated continuously in the plant of the builders in the past few years. It was originally designed to perform certain operations in their product, and proved to be such a success that they have decided to build a complete line of drill presses with this feature. Their long experience with it enables them to present it in practical form.

The knee is raised by a crank fitted to a steel shaft, with a pinion milled from the solid, meshing with a rack on the column. The rack is also of steel, with cut teeth. The universal joint for the work table is so designed as to give a rigid support to the table, with provision for drawing all bearings tightly together with the clump screws shown. A lock bolt is provided for setting the table accurately in 45 and 90 degree positions. The spindle is of special high carbon steel, carefully fitted, with the thrust taken by fibre collars. The hole is a No. 3 Morse taper. The column is heavy and secured to the base by a clamping bolt. The base is provided with T slots for clamping heavy work.

The machine may be provided in any of the following forms: With universal table or solid knee; with lever feed; with wheel and lever feed and quick return; wheel and lever feed, quick re-



Robertson's Universal Table Drill.

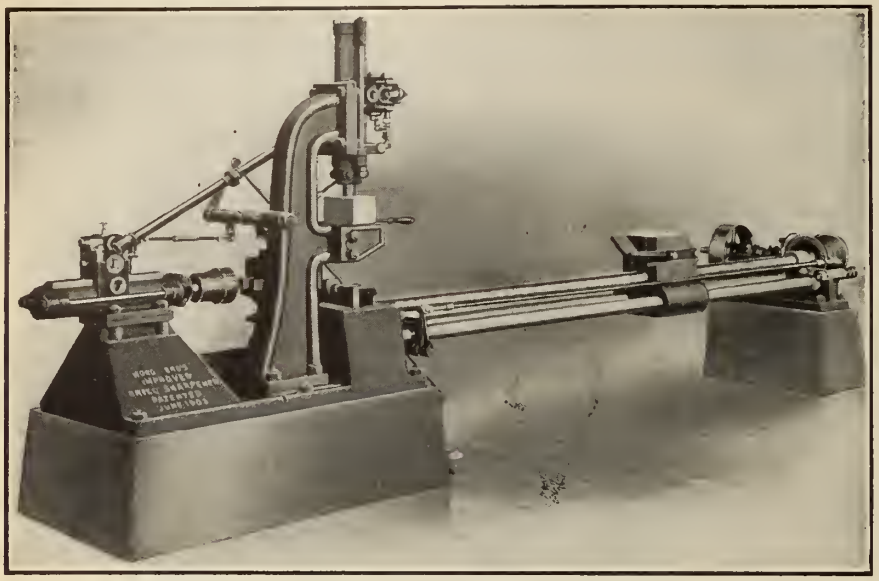
turn, power feed, automatic stop; it may also be furnished with or without back gears as desired. The bevel gears are planed from the solid metal and are provided with guards. The machine shown will drill to the centre of a 42-inch circle.

DRILL-MAKER AND SHARPENER.

The illustration herewith represents the Word Brothers drill-making and sharpening machine. It consists of a cast-iron bed plate with two power hammers, a vertical and horizontal, mounted thereon, and a dead block, carried by guide rods, which are attached to the bed plate.

The hammers are actuated by compressed air and are equipped with auto-

matic controlling valves which permit the operator to handle both hammers by a single foot treadle, which is pivoted under the hollow of his foot, thereby enabling him to operate the machine without moving his foot from one place.



Drill Making and Sharpening Machine.

By a pressure of the foot on the toe of the treadle the horizontal hammer is brought into action, the intensity and speed of the blows are governed by the pressure of the foot on the treadle; by releasing the pressure of the foot on the toe of the treadle the hammer is stopped by the controlling valve, which acts instantly, shutting off the supply of air to the hammer, bringing the piston to a retracted position and the foot treadle to a level, or central, position. By a pressure of the foot on the heel of the treadle the vertical hammer is started and stopped in the same manner. The foot treadle is always brought to a central or neutral position by the controlling valves when the pressure of the operator's foot is removed or is resting equally on each end of the treadle, and the pistons of the hammers, carrying the dies or hammer heads, are always brought to the upward or backward stroke and held there. These controlling valves prevent one hammer from coming into action while the other hammer is in use. Their importance, in a machine of this kind, is illustrated by the fact that the time required by them to stop one hammer, hang it up safely, and start the other hammer under a full head of air is one-tenth of a second.

In line with and moving to and from the horizontal hammer is the dead block, a massive casting faced with tool steel, which the drills or steels rest upon and which receives the impact of the horizontal hammer when it is in action. This dead block is supported by heavy guide rods securely bolted to the bed plate. It is moved by a screw, which, in turn, is driven by a friction gear running six hundred revolutions per minute. The dead block is adjusted to the different lengths of steels, accurately and quickly, by a slight pressure on a lever, bringing it forward or backward, as desired.

Between the horizontal hammer and the dead block are adjustable split dollies which work on the cutting edges of a drill, and which forge and sharpen all sized drills without any change. The horizontal hammer strikes these dollies rapidly, which are driven against the drill bit or steel, and which rebound slightly at every blow, permitting the scale from the steel to fall clear of the work, while the dollies are thus being struck they are opened and closed by a cam lever attached to the guides carrying them. This opening and closing of the dollies, while they are working on a drill or a blank piece of steel, prevents undue buckling or bending of the steel, as the dollies work only on two wings of a drill bit at a time, the other two wings of the bit bracing and supporting the wings thus being worked upon. This causes the metal in the wings of the drill to be equally distributed and hammered alike, so that the whole bit is a homogeneous mass of equal density and compactness, permitting the drill to take a high temper and stand up to hard work without broken corners or battered edges.

The vertical hammer carries dies suitable for the work to be performed and, like the dollies described above, they do not have to be changed in handling the different sized drills. The functions of the vertical hammer are to swage and gauge the drill bits and to properly shape the wings of a new drill.

The weight of the machine is four thousand pounds, they being compactly and rigidly built to stand the hard service required of them. Their capacity is from six hundred to eight hundred drills per day. The machine forges new drills almost as rapidly as it sharpens old ones.

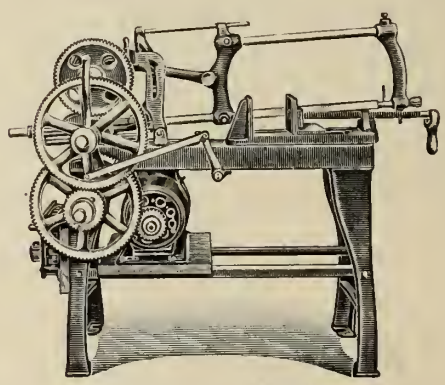
The machines are manufactured in Rossland, British Columbia; Houghton, Michigan, and San Francisco, California.

MOTOR-DRIVEN HACK SAW.

Application of the electric motor to a hack saw is illustrated herewith in that of the Robertson Manufacturing Co., Buffalo.

Because of the many uses and applications of these machines compact and close-connection was desirable, and was obtained by mounting the motor under the bed at the rear end, where it occupies no extra space. The starting box is mounted on the outside of the legs, also at the rear end. The pinion on the motor and the intermediate pinion are of fibre, metal bushed for set screws. The other gears are cut from solid metal. The motor is of ¼ h.p. and is furnished for either direct or alternating current.

The saw is of the company's regular type, having an automatic stop gravity feed and quick starting clutch. The one illustrated has an adjustable frame capable at its greatest extension of using a 17-in. blade for cutting stock up to 8x8 inch. For smaller work a shorter



Motor Driven Hack Saw.

blade can be used by adjusting the outer arm on the top bar. The equipment is one especially useful for cutting long stock in all shapes.

CIGAR HOLDER SOUVENIR.

A handsome cigar holder is being sent out as a souvenir by the Ludlow Valve Manufacturing Co., Troy, N.Y. No doubt the company will be pleased to send this souvenir to readers of Canadian Machinery if, when writing, they mention this paper.

Foundry Practice

MODERN IDEAS FOR FOUNDRYMEN

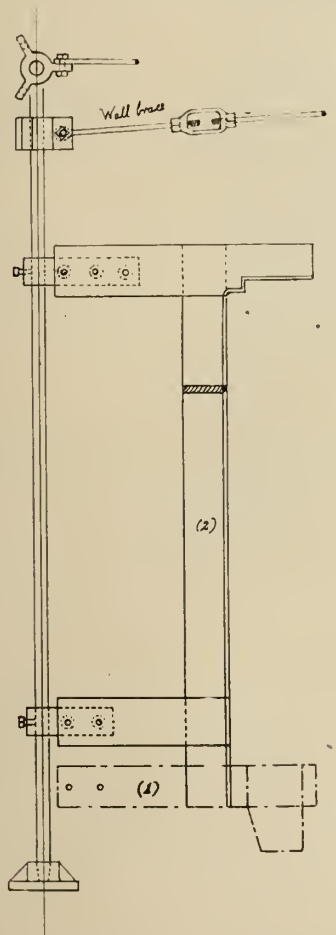
An Example of Loam Molding

A detailed description of the making and pouring of a loam mold for a six-foot pipe with a seven-foot rectangular branch.

By Jabez Nall.

ARTICLE I.

While the method of making molds for castings, by the use of a brick structure faced with loam, has in the present-day foundry practice been discarded to same extent in favor of the "skin-dried" mold, because of the less amount of labor and time required to produce the casting, with almost equal results, there are still many times when it is the only practical way to make castings of certain design. While the foundry expense



by this method may be high, there is often a corresponding saving in the pattern shop, and the finished casting is usually of a high grade.

There is another feature of the loam mold, that when the shape of the casting permits, the same mold can be used more than once; while we may not term it a permanent mold, we have known as many as 8 to 10 castings to be made from the same outside mold, with nothing more done to it, than the burnt blacking brushed off while hot, and a fresh coat applied, with possibly a little patching with fire clay. A new core is of course being provided each time. In such a case this style of molding cheapens production. Other points in its favor will be brought out later on.

It is therefore essential that the young pattern-maker, as well as the young molder, should make himself thoroughly familiar, not only with the principles, but with the details of this method of the production of castings.

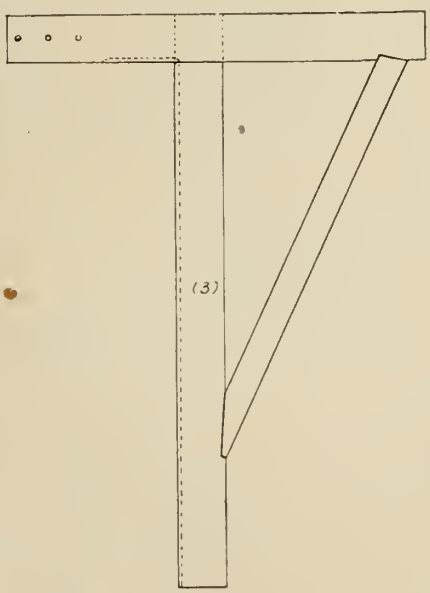


Fig. 1.

Pattern Work Required for 6-foot Pipe.

The example given in this article of a 6-ft. pipe with a 7-ft. rectangular branch, 1 in. metal thickness, has one or two special features that will be of interest. The work of the pattern-maker, on such a casting is not difficult or intricate and consists of the making of four sweeps or loam boards, as shown in Fig. 1: (1) Seat sweep; (2) Sweep for outer casing; (3) Sweep for centre core; (4) Sweep for face of branch core.

There is also the making of a skeleton pattern for the branch as shown in Fig. 2, which is a plan view on centre line. The upper half shows it used as a pattern for the mold, with ring for core print attached. The lower half of view shows the same used as core box. This branch is made in halves dowelled to-

The Finished Casting.

gether, and when used as a pattern a loose ring turned true on the outside is made for core print. This is made 12 in. wide to suit the brickwork, and is likewise cut in halves. Another ring of equal width turned true on the inside is made for a core box; this is left whole and the two halves of pattern secured to it, and used as indicated in Fig. 2.

The bottom flange is made in 12 segments, as shown. The cut mentioned, as at A, is not necessary in this case; but this flange may be used again on some other job, molded in reverse order, when this cut enables the molder to pull in the flange.

Better for Skeleton Pattern and Loam Board Not to Fit Closely.

Some patternmakers spend much unnecessary time and labor in carefully fitting even a skeleton pattern to a loam board; when it is better that they do not fit too close. Take this branch for instance, it is necessary that the three staves on the cardinal centres of

each half be correct, and these are easily got from the layout, but the rest should be well clear of the board and only approximately correct in the cut. The application of the principles of projection will readily give the lengths of each of these without any further trying. We have known one man to spend ten days on a job, and work harder than another man, who made a similar but larger one in three days. This may seem exaggeration, but is fact, and represents the difference between the cut and try and cut and try again system, and working to a correct line. But this, as Kipling says, is another story.

Making the Mold.

In commencing the mold it is necessary that the molder have his plans fully matured; he must know all that he is going to do from laying the first brick to taking out the casting. Usually he makes his own "rigging," and the first thing needed is a bottom, or foundation plate, which should be of ample size to support the brickwork for the centre core and the outside walls, including the branch; this should be about 3 in. thick and should be provided with lugs have cored holes for the binding bolts as shown in Figures 3, 4 and 5. This, as well as all the other plates, is cast in open sand. The spindle having been placed in the socket, plumbed up and secured at the top by the wall braces, sweep No. 1 is adjusted and three rows of brick laid on to form seat of mold. It is best that this be made deep, as shown, to ensure the mold returning exactly to the same place and to prevent any accident by straining at this point. A generous allowance of "mud" is placed between each brick.

In building any loam mold it is important that the brick be not too close, as to prevent proper venting. This done, it is daubed up with a coarse loam, well rubbed in by the hand, afterwards left for a few hours to stiffen before being given a thin coat of fine loam and placed in the oven to dry.

Other Rigging for Mold.

The molder then gives his attention to the other "rigging" required. This includes a lifting ring for lower half of mold, having three lugs for lifting purposes, one side being carried out to allow the building of the brickwork for the branch as shown in Fig. 5, and two rings for the joint of mold at centre line of branch. These two rings may be cast in the same open sand mold, by making it of sufficient depth for the two, first pouring the lifting ring for the top half of mold, which must be strong enough to carry the superstructure without springing, and provided with three lifting lugs similar to bottom lifting ring. After the iron is set, parting sand is thickly strewn on, and the other ring poured on top about 1 in. thick. Three holes are cast in these plates in which socket and pins for dowels are afterwards inserted, thus bringing the two halves of mold correctly together after being separated.

A top or covering plate is made having bolting lugs to match foundation plate, and also having eight holes for the pop gates at top of mold, two holes for risers, one to come in top flange and the other at the highest point of the flange on branch, and three supporting rings for the centre core, these being about ¾ in. thick and 7 in. wide, allowing 2-in. of space between the outer edge and face of core; these supporting rings are also split to allow for placing in position without removing braces from spindle, and to allow for contraction of casting. This rigging can be readily traced by referring to Figures 3 and 4.

In addition to the foregoing, an arbor or lifting plate for the branch core must be made, as shown in Figures 3, 4 and 5. This is provided with two loops for lifting hooks, another hole cast in the outside plate, allowing for a third hitch. A turnbuckle can then be used with this greatly facilitating the setting of the branch core.

This completes the rigging required for the job, the 5-ft. pulley ring, and stands, as well as the 4-way cross used in clamping the mold are foundry stock.

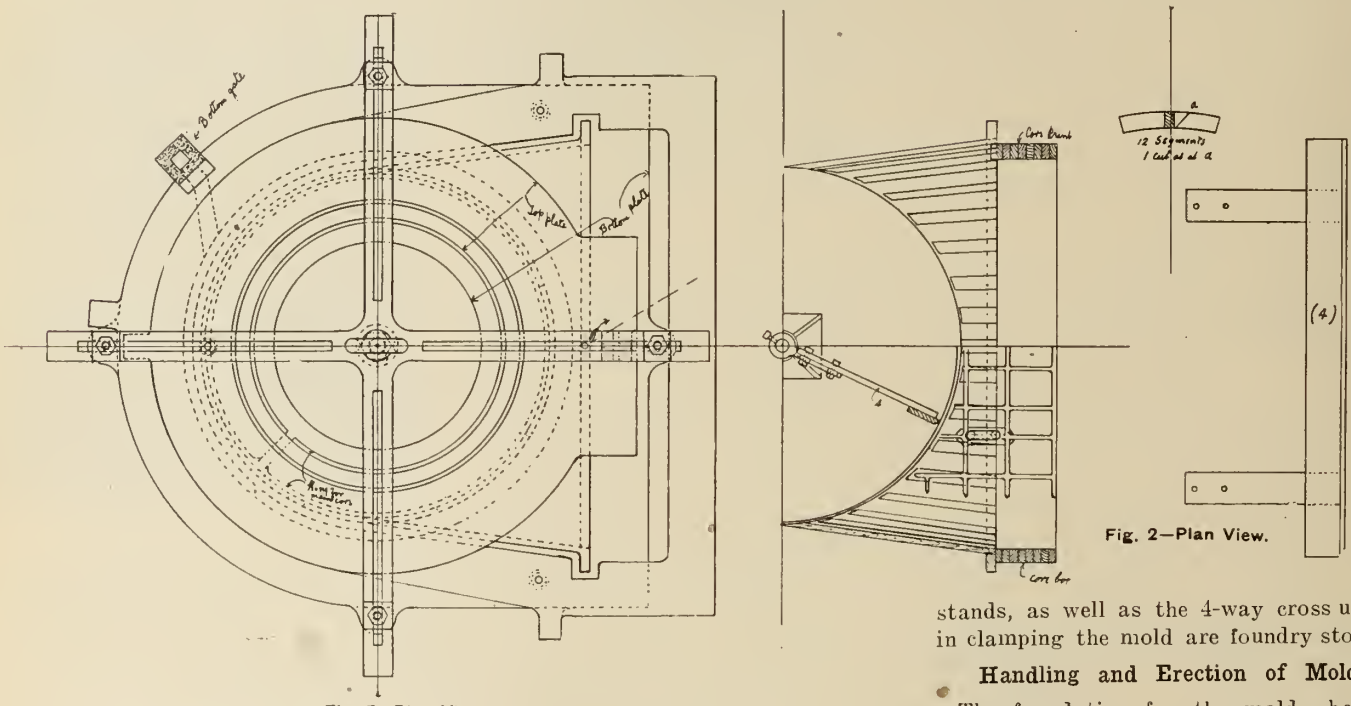

Fig. 5—Plan View.

Fig. 2—Plan View.

Handling and Erection of Mold.

The foundation for the mold, being dry, is placed in a pit of sufficient depth, to allow for the easy pouring and handling of casting. This would be governed by the conditions of the foundry as regards condition of floor, head-room, crane capacity, etc.

This plate, being set and levelled, and the spindle being readjusted, board No. 2 is attached, the lower flange set, and the joint covered with paper to ensure a true parting. The lower lifting ring is set in a bed of coarse loam, and on this the outer wall is built to the height of the lower edge of the branch flange. The half of the skeleton pattern, with core print attached, is set up and braced in place, the building of brickwork continued to the centre line, the loaming up of the branch keeping pace with the building of brickwork. At the top the parting ring is set to hold

the structure together and make a level joint. The face of the mold is then given a coat of coarse loam ½ in. to ¾ in. thick, well rubbed in by the hand, and its face regulated by the sweep board. After this is set a finish coat is applied as usual by the sweep.

The joint being sufficiently set, the upper lifting ring is bedded in place and the top half of mold made in like manner. Care must be given to the arching of brickwork over the branch. This and the outer wall should be not less than 9 in. or a full brick in thickness. We have known a lighter wall to result in the loss of the casting from the fact that the wall was not strong enough to resist the ramming outside, notwithstanding that when the mold was closed it showed up correct in thickness when tried by gauges. The wall crowded in at the top until, instead of 1 in., only 7-16 in. was left, and it was impossible to know this until it was found by the casting cracking as a result of strain owing to uneven thickness of metal.

Care should be taken to support the small amount of brick behind the branch flange by ½-in. iron rods, and, for easing the vent at these points, a few straws cut square at the ends, laïd in among the loam between the bricks, will make excellent pipes to carry off the gases. The outer casing complete, with the top flange swept in, the whole is given a good coat of blacking. The top half lifted off and placed in the oven to dry, the branch pattern withdrawn, the lower half is also lifted away and dried. Board No. 2 having been taken off, spindle board No. 3 is adjusted and the centre core built up in position; after finishing it is covered with sheet iron and dried in place.

In order that the two cores may be built at the same time another spindle is set up and the branch pattern with core ring attached is braced plumb and level. Board No. 4 is attached to this spindle as shown in Fig. 2. The face of this board is set at ¼ in. greater radius than radius of centre core; this allows of the two cores abutting in the centre without crushing the weak points of core when being set in mold.

In making the branch core it is necessary that some false work be built to form a bed as far as the core arbor reaches; or that the arbor be placed reverse side up and filled in with wedged brick and loamed up to a segment, then turned over and placed in position. The brick in the open spaces at the ends should be secured to the arbor by wiring them together. The arch is then carried over as indicated in Fig. 4. Two holes must be left at the top for insertion of lifting hooks. The face of core is built up a half brick wide and loamed up to the board, the thin points supported by rods running well back between the bricks. The other part of the core is filled with dry brick, and the holes for lifting hooks are filled in, after the core is placed in the mold.

The top or covering plate having been placed reverse side up, it is given a coat of loam, holes being left for the pop gates and risers aforementioned. It is then dried. The mold can now be assembled as shown in Figures 3 and 4.

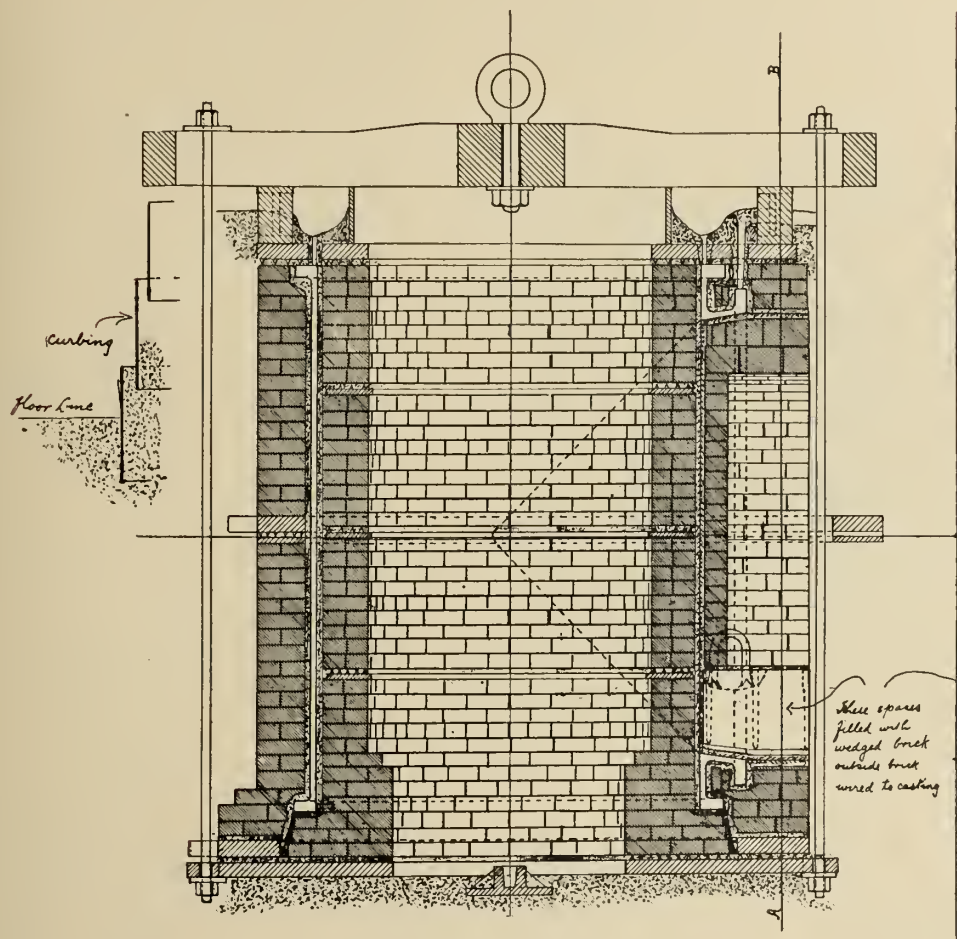

Fig. 3—Section through centre line of mold

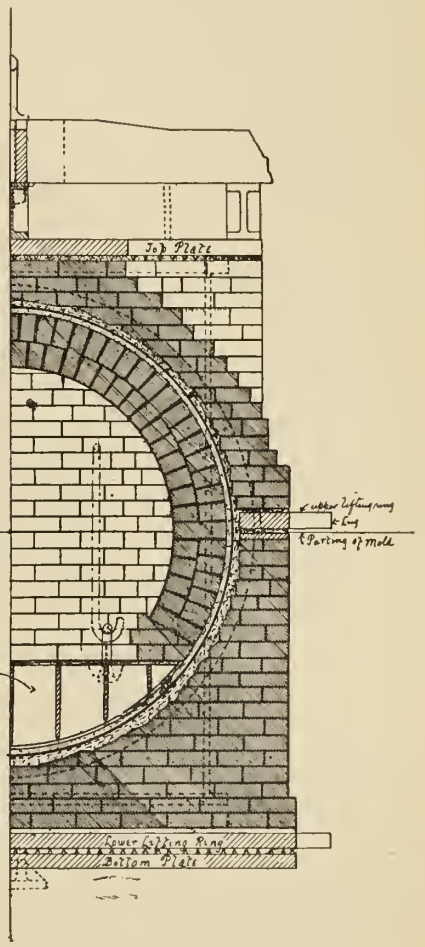


Top Plate
Parting of Mold
These spaces filled with wedged brick outside bricks wired to casting
Lower Lifting Ring
Bottom Plate

Fig. 4

Molding the casting this way gives the molder a chance to watch his metal thickness and see that no crush or other accident happens as he goes along.

The whole being secured to the satisfaction of the molder, the outside ramming is now made, gate cores being set, as indicated in Fig. 5, connecting with the lower flange, vents being cared for by stakes or rods placed while ramming and drawn up and afterwards removed. A straw rope connected to any special part will carry the vent in any direction desired. This outside ramming

having been carried up to about a foot below the top of foundry floor, curbing is set, as indicated to the left of Fig. 3, and the ramming carried up to the top of mold, the bottom gate being connected to the top by dry sand cores. Plugs are placed in the risers and top gates aforementioned and runner and flow-off built, the latter in any convenient direction.

Pouring and After Handling.

A double pouring-basin is made having the level for bottom gate about 4 in. lower than the one for the top gates. In pouring the metal the bottom gate is poured first until about 2 ft. high in the mold, when the ladle is tipped or basin flowed over and the bulk of metal poured in from the top. The bottom gate set as shown gives a whirling motion to the metal, and in coming from the top the metal does not have a chance to cut the sand and breaks up any slag or impurity that has entered the mold, and prevents any cold shot.

About an hour, or less, after pouring, the brickwork of the centre core should be split to allow for the contraction and prevent any shrinkage strain in the thin metal. If the metal were thicker this might not be necessary. This operation must be begun at the bottom. To do this it is necessary that a man enter the mold from the top. No man should be left in for more than five minutes at a time, and as the whole operation will take fully fifteen minutes, three or four changes will have to be made. It is an undesirable and dangerous job an account of the gas, and could easily be done away with by use of a cheap mechanical device; but tools cost money and in the foundry labor is cheap.

This accomplished, we can only wait to see the casting as shown in photo, Fig. 6.

The Grey Iron Foundry as a Business Venture †

By Thomas D. West, Sharpsville, Pa.

This article describes what a man embarking in the grey iron foundry business, should know before he begins what methods to pursue after he has decided to start, and what obstacles he is likely to encounter. Each sentence forms the text for a paper in itself, but taking the first, the main point which should be considered in starting a foundry, we have the following :

First—The great lack of good skilled labor.

Second—Influences retarding the training of a plentiful supply of skilled mechanics.

Third—Independence and insubordination of many of the few skilled and respectable men available that may be obtained after extra inducements are made for their services.

Fourth—Difficulties and losses arising from trying to do work with the riffraff that a starter is compelled to employ in beginning operations.

Fifth—The slow attainment of discipline and organization in a shop's working force.

Sixth—Losses through defects developed in machinery and tools caused by trying them out and bringing them into good working order.

Seventh—The advantage that sellers of appliances and purchasers of castings take of ignorant beginners.

Eighth—Extra risks with consequent losses by accidents incurred through the want of experience in operating machinery and shop appliances.

Ninth—Difficulties in obtaining practical and good executive managers and foremen.

Tenth—Losses and embarrassment caused by the narrow range of vision of hired managers, as compared with that of the man who may have his all at stake striving for a foothold.

Eleventh—Inability of proprietors, inexperienced in actual molding, mixing and melting, to avoid mistakes in getting the best managers and foremen, the windy blow-hard being often better liked than the one of true merit because of inability to rightly judge.

Twelfth—The underestimation of the obstacles and uncertainties that every beginner must encounter.

The twelve points just given are as a whole encountered much more in brisk than in dull times, and in times of very great prosperity can be the means of driving the most experienced workers and financial managers to the wall.

A beginner's fight to exist can be such, even with sufficient working capital, that he is brought to the point of despair of success by reason of the great odds and seemingly insurmountable difficulties that will confront him.

The difficulty of obtaining good overseers as well as skilled labor, which is most pronounced in good times, is alone one of the twelve factors that demands more consideration than a reasonable working capital, and often knocks out the best of experience, good management and hard work.

We could take up every one of the twelve points and fill a number of pages with a discussion of them, but will let it go with the simple statement. Aside from the great need of skill, the general public's great lack of comprehension as to the demands on skill and experience needed by our molders in connection with the making of castings is about the next greatest evil to injure many starters and the trade in general. This poor conception that the general public has of the foundry business has caused many novices to undertake the work and there is one instance that recently came to the writer's notice in which a bookkeeper who never lifted a rammer put all his hard earned money into a small foundry and hired a farm hand to run it for him while he maintained his salaried position. This new foundry owner was a bright and modern financier and when his working capital was exhausted he did not close his shop until he had involved others in his downfall.

There is one feature difficult to comprehend and that is the great difficulty of making men inexperienced in the business realize its hazard as well as the fact that skill is required to make good castings. Of course almost any fairly intelligent man can make a good casting, of almost any character, allowing him time to experiment, and where there is sufficient capital and cupola capacity to keep re-melting his bad castings. Few beginners, however, have sufficient assets to support this experimental work.

The novice's inability to understand the requirements for making good castings at the first pouring is such that even men that can successfully make small and medium castings day in and day out believe that they are competent to be trusted with the making of most any heavy castings. When this belief can be found so prevalent, as it is with molders throughout the world, is it any wonder that many who have walked through a foundry a few times get the idea that all is easy, and that nothing else is required than a few patterns and sufficient muscle to pound sand, under the control of an intelligent business head to make a foundry pay, ever forgetting that intelligence is one requisite and experience another.

The question of the methods a man should pursue, who has decided to start a foundry is answered as follows :

First—He should make a thorough investigation to discover if there is a demand for the class of castings he intends to make, and what competition exists.

Second—The selection of a site that will be central to his market, and in

† Paper presented before American Foundrymen's Association.

building to start on as small a scale as practical, but planned for extensions that can be carried out without tearing down too much of the existing plant.

Third—In the search for machinery and appliances he should endeavor, as far as possible, to get the experience of others. The A. F. A. convention should be visited for its information and its exhibits inspected to note and investigate the latest improvements.

Fourth—In buying machinery and applianees he should avoid, as far as possible, the purchase of second-hand tools. The new has all its life, whereas the old is more or less worn out, and will not as a rule give good service for the money expended.

Fifth—One seeking orders, and not competent to quote prices, should not be ashamed to seek his manager's or foreman's adviee.

Sixth—In starting to make castings don't be in a hurry to fill your shop with work. Go slow, feel your way, and your chances for error or failure will be greatly decreased.

Seventh—Be sure to have suffieient working capital and good chanees of obtaining a surplus over and above what is considered necessary.

As to what a man should know before he begins is rather a broad question to ask an experieneed founder, with the expeetation of getting any answer other than that he learn to be a thorough molder as well as a business manager. No man who intends to be at the head of a foundry can be too thorough in the aetual work of molding, mixing and melting, and he should have exeeutive and business qualifications.

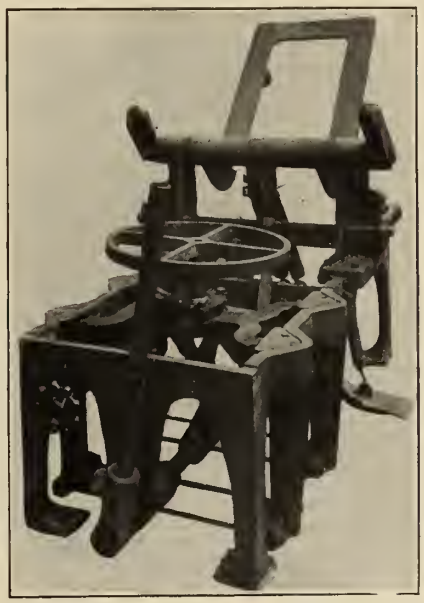
There is no trade demanding so mueh skill and experience wherein so many enter who are wholly defieient in praetieal knowledge of its operations as a foundry business. It is a ease of the many trying to make two wrongs make one right, and beeause some learn of an inexperieneed man having made a suecess of his entry into the field they think they ean do likewise.

Thirty years ago, few, if any, ever thought of going into the foundry business if they were not so praetieal that they could discharge any molder and take hold of his work in a more masterly manner. To-day we find bankers, lawyers, and even elerical men, who have assumed the management of foundries. We must ever remember that brains and intelligence do not stand for experience. If the day ever comes when praetieal edueation is given greater recognition, we will have the best that is possible in the foundry president or manager, as well as in the employe, but not before.

NEW MOLDING MACHINE.

Accompanying is an illustration of the molding machine recently placed on the market by J. N. Paxon Co., Philadelphia, the Glenwood Rockover machine.

The chief advantage of this machine, as outlined by the makers, is that the regular hand patterns can be used by fastening them to a board, if they are flat backs, or if irregular shape, by making a cope and drag hard match, the pattern being used for making all the drags; then being placed in the match for making copes, at the same time not interfering with their usefulness as a hand pattern. The parts of the machine are all interchangeable. It is made as low as possible, so that it is convenient for a man to "tread off a mold," also by dropping the mold away from the pattern, as is done in this



Glenwood Rock-Over Moulding Machine.

ease, it leaves the mold resting on the frame at a height that is very convenient to be taken away.

The machine is arranged so when the mold is rolled over in position to have the pattern drawn, the mold earrier is rigidly locked in a position exactly at right angles with the ways. It is also furnished with means of adjustment for wear, so that the match carrier ean always be kept in this position, and as it is locked it allows the operator to give his undivided attention to the next operation, and after the pattern is drawn, the locking is released by a foot treadle, placed convenient for the operator. The mold carrier being counterbalaneed by springs with a takeup, so that more or less tension ean be readily applied to the mold carrier, to counterbalance the different weight of match.

The machine is equipped with a very simple and effective evening device (as shown in illustration). By a hand wheel convenient for the operator, this evening device is released, and at the same time the table is brought up under the bottom board, and without any resistance, is allowed to take a seat firmly under the board, and by revolving the hand wheel, it is then clamped firmly into position, so that if a mold is of uneven weight, on the different sides, it will fall away from the pattern in a perfeetly straight line.

The lever for dropping the mold is arranged on a toggle joint, so considerable movement of the lever is neeessary at the starting of the molding, in order to move the mold very little, insuring thereby an even drop, and on account of the leverage, it is very easily manipulated by one hand of the operator, allowing him with the other hand to give attention to the clamp on the evening device, and if a vibrator is used, also to operate this device at the same time.

CONVENTION NUMBER OF BLAST.

The June issue of "Blast," a periodical issued by the Detroit Foundry Supply Co., Detroit, is devoted to a resume of happenings at the Philadelphia convention of the American Foundrymen's Association. The editor of this number has shown that while attending very much to business at the convention he was far from being oblivious to the humorous happenings. Those not having already received a copy of the issue should do so by applying to the Detroit Foundry Supply Co., mentioning this paper.

ASSOCIATION OFFICERS

AMERICAN FOUNDRYMEN'S ASSOCIATION.

President—S. G. Flagg, Jr.

Vice-Presidents—C. J. Caley, John S. Burr, H. E. Field, J. H. Whiting, A. K. Beckwith, T. N. Sheriff, J. P. Golden, L. L. Anthes.

Secy.-Treas.—Richard Moldenke, Watchung, N.J.

BRASS FOUNDERS' ASSOCIATION.

President—Chas. J. Caley.

Secretary—Andrew M. Fairlie, Philadelphia.

Treasurer—J. H. Sheeler.

FOUNDRY SUPPLY ASSOCIATION.

President—E. H. Mumford, E. H. Mumford Co., Philadelphia.

1st Vice-President—W. P. Shepard, Rogers, Brown & Co.

2nd Vice-President—W. S. Quigley, Rockwell Engineering Co.

3rd Vice-President—H. E. Atwater, Osborne Mfg. Co.

4th Vice-President—Wm. Chambers, Garden City Sand Co.

Treasurer—J. S. McCormick, J. S. McCormick Company.

Secretary—H. M. Lane, Cleveland.

Trustees—W. E. Kanavel, Interstate Sand Co.; E. J. Woodison, Detroit Foundry Supply Co.; W. J. Thompson, Hamilton Facing Mills Co.; F. W. Perkins, Arcade Mfg. Co.; and Geo. Rayner, the Carborundum Co.

AMONG THE SOCIETIES

SOCIETY OFFICERS.

Canadian Mining Institute.

President, George R. Smith, Thetford Mines, Quebec; secretary, H. Mortimer Lamb, Victoria, B.C.; treasurer, J. Stevenson Brown, Montreal.

Toronto Branch A. I. E. E.

Chairman, R. G. Black; vice-chairman, K. L. Aitken, secretary, R. T. McKeen.

Marine Engineers.

Grand president, E. J. Henning, Toronto; grand secretary, Neil J. Morrison, St. John, N.B.

Canadian Electrical Association.

President, R. G. Black, Toronto; vice-presidents, R. S. Kelch, Montreal, W. R. Ryerson, Niagara Falls, Ont.; secretary-treasurer, T. S. Young, Confederation Life Building, Toronto.

Canadian Association of Stationary Engineers.

President, W. A. Sweet, Hamilton; vice-president, Jos. Ironsides, Hamilton; secretary, W. L. Outhwaite, Toronto.

Canadian Railway Club.

President, W. D. Robb; secretary, James Powell, chief draughtsman motive power department, G. T. R.; treasurer, S. S. Underwood, chief draughtsman car department, G. T. R.

Engineers' Club of Toronto.

President, C. B. Smith; secretary, C. M. Canniff, 100 King Street W.; treasurer, John S. Fielding, 15 Toronto Street.

Canadian Society of Civil Engineers.

President, W. McLean Walbank; secretary-treasurer, C. H. McLeod, Rooms, 877 Dorchester street, Montreal.

Society of Chemical Industry

Chairman, Prof. W. H. Ellis; vice-chairmen, H. H. Van Der Linde, Milton; H. Hersey, A. McGill; hon.-secy., Alfred Burton, 44 York Street, Toronto.

Ontario Land Surveyors.

President, Otto J. Klotz, Ottawa; vice-pres., Thos. Fawcett, Niagara Falls; secy.-treas., Capt. Killaly Gamble, Toronto.

CONVENTION OF STATIONARY ENGINEERS.

The eighteenth annual convention of the Canadian Association of Stationary Engineers will be held in Guelph from the 13th to the 15th of August, inclusive. The city will assist the local engineers in making this convention a success.

AMERICAN CHEMICAL SOCIETY.

The semi-annual meeting of the American Chemical Society was held in the Chemistry and Mining Building of the University of Toronto on the last days of June. Many important papers were presented and discussed, most of which were of a very scientific character. A visit was made to Guelph to inspect the Ontario Agricultural College, and a party took a trip to Cobalt, where there is much to interest such a body of men.

The paper which was of the greatest interest to the commercial world at present was that presented by E. G. Acheson, the Acheson Graphite Co., Niagara Falls, N.Y. and Ont., on "Deflocculated Graphite." Mr. Acheson has developed the manufactuer of artificial graphite in the electric furnace, and in the last year or two he has developed a method of suspending very finely powdered graphite in oil for purposes of lubrication. He is arranging for manufacturing based on this new method.

The American Chemical Society has a membership of over 3,000, and ranks in standing with kindred societies in Great Britain and Germany. It differs from these, however, in that industrial chemists as well as students of pure science are included in its membership. In fact, industrial chemists form a large percentage of its members.

There were quite a number of Canadian chemists present at the convention, and no small compliment was paid Canadian chemists by the president when he said in his opening address that the society's meeting in Toronto was an acknowledgement of work accomplished in chemistry by Canadians.

American Institute of Mining Engineers

Summer Meeting of A.I.M.E.—Reception by City and Provincial Government—Visit to Cobalt District.

The summer meeting of the American Institute of Mining Engineers was held in Toronto, July 22-29, with headquarters at King Edward. The members were received by the city and Provincial Government. They held business sessions the first two days, then left on special government train for Cobalt and districts nearby, where they inspected different mines.

What the Institute is For.

The American Institute of Mining Engineers is one of the most important technical societies in the world. It was organized in 1871, and has a membership of over 4,000. While most of the members are residents of North America, its membership embraces leading mining engineers, metallurgists and geologists of nearly all countries in which the mineral industry has been developed.

The president of the institute usually holds office for two years. John Hays Hammond the eminent mining engineer, was elected to the office during the present year. The secretary of the institute during the past 36 years has been Dr. R. W. Raymond, one of the world's most renowned mining men.

The headquarters of the institute are in New York. The United Engineering Building, opened about a year ago, which cost $1,500,000, a gift of Andrew Carnegie, now houses the institute, together with the sister societies of Mechanical and Electrical Engineers.

In addition to the publication of technical papers, the institute yearly organizes excursions to various mining centres. In 1901, for example, the excursion consisted of two special trains from New York City to Mexico and return. In 1905 the excursion of the institute was to British Columbia and the Canadian Yukon. On the invitation of the Iron and Steel Institute the American Institute held its summer meeting in England in 1906.

Reception and Business Meetings.

It was through the efforts of Hon. Frank Cochrane and Professor W. G. Miller, that the meeting of the institute was held in Canada. The Government and civic authorities welcomed and gave receptions to the members, and entertained them while in Toronto. At the business sessions several important papers were presented and some valuable addresses given. Among the papers were: Destruction of Salt Industry at Salton, Cal., by Prof. W. P. Blake; Some Reflections on Secrecy in the Arts, by Dr. James Douglas, New York; in which the author advocated that there be less secrecy maintained regarding industrial processes; Coal Briquetting in the United States, by Edward U. Parker, Washington.

Should Be No Railway Subsidies.

Dr. James Douglas, a Canadian now living in New York, entered a strong protest against the subsidizing of railroads in Canada. That was one feature that had always struck him as objectionable. In the United States they had never experienced difficulty in getting money with which to build a railroad if from an economic and commercial point of view a railroad was required. When they bought the votes of a district by subsidizing a railway they introduced into their politics the very worst possible element of corruption. As a Canadian he thought a protest should be made against the practice. On the other side of the line they were suffering from congestion on their railroads, but that state of matters would never come in Canada so long as they continued the nefarious method of depending on the Government for assistance instead of depending on themselves.

An address on the Tar Sands of Athabasca was given by Dr. Robt. Bell, Ottawa. He knew of no other place in the world in which there was so great an accumulation of tar sand, formed by the outpouring of petroleum, as in the valley of the Athabasca. The sandbeds, he estimated, covered 1,350 square miles and had an average depth of 150 feet. They formed a valuable asset in that they could be used in the manufacture of oil and fuel, paving and roofing.

The electric air drill, an invention of great importance to mines, and one upon which Mr. Edison and Professor Elihu Thompson spent hundreds of thousands of dollars and worked for years, was explained by Mr. W. L. Saunders, New York. Mr. Edison was baffled, and declared that the electric drill was a failure. Professor Thompson continued his efforts, and it was to him that the credit of the invention of the electric air drill was due. It had been a long and costly battle, but the drilling of rock by electricity was no longer a theory, but a fact.

Cobalt Mines Unique.

Prof. W. G. Miller, the provincial geologist, read a paper on the subject of the Cobalt mineral area. The district, he said, was unique. There was no other place on the North American continent where the association of minerals was of the same character, including high values of silver, nickel and arsenic. Only in Saxony, Bohemia and France were similar formations to be found. Prof. Miller referred to the large production in Ontario of corundum and mica. The greatest nickel mine in the world—the Creighton Mine—was situated also in the province.

The Cobalt region had gone ahead because of the silver alone for the Cobalt, nickel and arsenic had been practically lost. By perfecting the methods of refining there was no doubt that the ore would bring higher prices. There was no exact information but Prof. Miller estimated that the production of silver would be 7,000 tons this year.

Trip to Cobalt.

The members of the Institute went to Cobalt as the guests of the Provincial Government, by special train, and spent several days inspecting mines around Cobalt and other districts.

TORONTO ENGINEERS' OUTING

On July 26 the annual outing of the Engineers' Club, of Toronto, took place. It consisted of a trip by private electric car to Jackson's Point on the Metropolitan Railway. Stops were made at different points of interest along the newly constructed line. At the Point members interested themselves by boating, fishing, quoits, etc. An enjoyable day was spent.

Industrial Progress

CANADIAN MACHINERY will be pleased to receive as confidential industrial news of any description the incorporation of companies, establishment or enlargement of plants, railway, mining or municipal news.

New Plants and Additions.

A steel keg company may locate in Welland, Ont.

A gas company has been formed at Waskada, Man.

The new Rideau rink at Ottawa will cost $20,000.

A malleable iron works will be established at London, Ont.

The Labatt Co., London, will soon erect some new buildings.

Westman & Baker are to erect an $8,000 factory in Toronto.

The Maritime Engineering Co., Moncton, N. B., have sold out.

Chadwick Bros. are just installing a four-spindle cock grinder.

The Hull Electric Co., Hull, Que., is making additions to its plant.

An up-to-date pumping station is to be installed in Cobalt, Ont.

The Albion Stove Works, Victoria, B.C., are extending their foundry.

The Clark Foundry Co. will erect a large foundry in Sydney, N.S.

The Fairbanks Scale Co. will erect a large plant at Sherbrooke, Que.

Swift, Copeland & Co., Montreal, are building a factory in that city.

McIlwraith & Austin, founders, Listowel, Ont., have dissolved partnership.

A steel bridge will be built across the Humber river at Lambton, Ont.

The Winnipeg Casket Co. will build a factory at Winnipeg to cost $40,000.

The lift lock on Trent Valley canal at Kirkfield, Ont., has been opened.

A large car shops will be built in New Westminster, B.C., costing $200,000.

The plant of the Standard Chain Co., at Sarnia, Ont., will cost $40,000.

There is a splendid opening for a foundry and machine shop in Prince Albert.

The Freyseng Cork Co. are making a $7,000 addition to their Toronto plant.

The Berlin Machine Co., Hamilton, will erect a brick factory costing $150,000.

J. J. Heffron & Co., mattress manufacturers, Toronto, have been burned out.

Adam Beck will build a large extension to his box factory at London, Ont.

The Silica brick making plant at Parson's Bridge, B.C., is in running order.

The Vancouver Structural Steel Works will erect a large plant at Vancouver.

Joseph Gray, Peterboro, Ont., will move and considerably enlarge his lath mill.

The sawmill plant of A. Cooper, at Ouiment, Ont., has been destroyed by fire.

The Alberta Brick Co., Medicine Hat, turned out their first lot of bricks lately.

A Toronto brick company will develop the sand deposits near Vancouver, B.C.

Picard & Lalonde, machinists, Montreal, are spending $13,000 on new machinery.

The Dominion Cartridge Co., Montreal, will erect a factory at Brownsville, Que.

Michigan interests are contemplating the erection of a pulp mill at Sarnia, Ont.

The Electric Repair & Contracting Co., Montreal, will move to larger premises.

The warehouses of the Berlin Omnibus Company were totally destroyed by fire.

The Colonial Weaving Co., Peterboro, will build a large addition to their plant.

The Waterloo Threshing Company may build a $200,000 plant at Portage la Prairie.

T. Dexter & Son, London, are remodelling their flour mill to 200 barrels capacity.

The Canadian Iron and Foundry Co., St. Thomas, Ont., will extend their works.

The International Snow Plow Co., Stratford, will manufacture steel box and flat cars.

The sewage disposal plant at the Woodbine, Toronto, is now run by Niagara power.

Sydney Smart, contractor, has installed a compressed brick plant at Malfort, Sask.

Carley & Wellard have commenced a furniture and cabinet making business in Winnipeg.

The Ham & Nott Co., Brantford, will double the size of their plant, at a cost of $40,000.

The Welland Vale Manufacturing Co. will greatly increase its plant in St. Catharines.

Safes made of concrete, reinforced with twisted steel, have been found very satisfactory.

J. B. Rouse & Co., Brantford, have sold their machine shops to Harris, Herod & Co.

The sawmill and electric light business of Geo. Leighton, Harriston, Ont., is for sale.

The International Steel Co., Montreal, have opened a branch at 50 Adelaide St., Toronto.

The warehouse and sheds of the Imperial Oil Co., Brandon, were destroyed by fire recently.

A large brick making plant will be erected at Cote St. Paul, Que., by D. G. Loomis & Sons.

The power house at Lake Ontario park, Kingston, Ont., was destroyed by fire recently.

The Lethbridge Electric Light Co., are installing a Babcock & Wilcox water-tube boiler.

The Morden, Man., Electric Light Co. will move their plant to the Okanagan Valley, B. C.

By a recently discovered process, alcohol can be made from peat at a cost of 6 cents per gallon.

The Polson Iron Works, Toronto, are building a dredge for the Pacific coast to cost $150,000.

Operations have commenced in the new glass factory of the Crystal Glass Co., at Sapperton, B.C.

Plans are being prepared for a $75,000 structure for the Canada Steel Goods Co., in Hamilton.

The Canada Spool Cotton Co., Maisonneuve, Que., are considering the erection of a new plant.

The International Heating and Light Co. will erect a gas plant in Edmonton costing over $1,000,000.

The shingle mill of G. Le Clair at Hastings, B.C., was damaged by fire to the extent of $25,000.

A large factory is to be erected at Lindsay, Ont., by Mr. Kennedy, late of Kennedy, Davis & Son.

The Canadian Cutlery Co. wants to build a plant in Grimsby, Ont. A loan of $25,000 is wanted.

The Canada Screw Co., Hamilton, are contemplating an addition to their plant to cost $150,000.

The Belleville Rolling Mills are running night and day, not being able to keep up with the demand.

The Otto Higel Co., Toronto, are installing Chapman double ball bearings in their new addition.

A plant for the automatic making of fruit cans has been installed by the Acme Can Works, Montreal.

The Canadian Government will establish a wireless station on the Government steamer "Inadra."

The Copper Smelting Co., Pictou, N.S., recently turned out a carload of copper matte worth $600.

The Colonial Weaving Co., Peterboro, will erect a new factory and install machinery costing $30,000.

The Montreal Pipe Company, Londonderry, N. S., will install a plant for the manufacture of car wheels.

The Goold, Shapley & Muir Co., of Brantford, will erect an addition to their plant, costing $27,000.

Keenan Bros., Owen Sound, are installing Chapman Double Ball Bearings in their new box factory.

The new mill of the Lake of the Woods Milling Co. at Keewatin, which cost $1,250,000, is in operation.

The Waterton Land and Power Co. will erect a saw and planing mill at Lethbridge, Alta., to cost $40,000.

Fire in the foundry of William Coulter & Sons, Toronto, damaged the premises to the extent of $400.

The Standard Shirt Co., Montreal, will erect a new factory on Delorimer avenue, Montreal, to cost $100,000.

The acid plant of the Dominion Pulp Mill at Chatham was completely destroyed by fire; damage, $11,000.

Messrs. Babcock & Wilcox, Montreal, are supplying 2,000 h.p. additional B. & W. boilers,

with superheaters and chain grate automatic stokers to the Canadian Pacific Railway Co.'s Angus shop.

The Nye Canning Co. and Cotton Shingle Mill Co., Vancouver, were destroyed by fire at a loss of $10,000.

The machine shop of John H. Hall, Brantford, will in future be under the name of John H. Hall & Sons.

The Berlin Machinery & Tool Co., Beloit, Wis., have commenced the erection of their plant at Hamilton.

The Canadian Billings & Spencer Co. are completing their plant in Welland. They will make drop forgings.

The Northern Engineering and Supply Co. have commenced work on their new Fort William, Ont., building.

The Montreal Terra Cotta Lumber Co., Montreal, are equipping their plant at Maisonneuve with electric motors.

The Canadian Machine Telephone Co., Toronto, is starting work on the installation of its plant at Lindsay.

A fixed assessment has been granted by Midland to the Canada Iron Foundry Co., and Midland Engine Works.

All the material for the smelter at Trout Mills, Ont., is on the ground and erection will commence immediately.

Beniss Bros. Bag Co., Boston, will erect an enormous plant at Welland, Ont., the plant alone costing $1,500,000.

The Canada Woodenware Company, whose plant was recently burned at Hampton, may build at Fairville, N.B.

The Maritime Mfg. Co., clothing manufacturers, Pugwash, N.S., will erect a three-storey brick factory, 75x40 feet.

The Canada Woodenware Co., whose plant at Hampton, N.B., was destroyed by fire, will rebuild at Fredericton, N.B.

The Rainy River Development Co., Fort Francis, Ont., are erecting a power plant to generate 65,000 horsepower.

The Montreal Rolling Mills will erect a large galvanizing plant. They are also increasing the capacity of their wire mill.

Work is progressing rapidly on the construction of the power plant of the Stave Lake Power Co., Stave Lake, B.C.

O. H. Bell and G. Harold, Owen Sound, will erect a $18,000 furniture factory in that town. The town has granted a loan.

The Wilcox Hardware Manufacturing Company, of London, is contemplating the installation of a large molding plant.

A company, capitalized at $150,000, is being formed in Pembroke, Ont., for the manufacture of alumina and its by-products.

The Hayne Milling Co., Bridgen, Ont., have let the contract for the remodelling of their mill to R. Whitelaw, Brantford.

An air compressor of 5,000 horsepower capacity is being installed on the Montreal river. The air will be piped to Cobalt.

The Renfrew Power Co., Renfrew, Ont., have increased the output of their plant to 1,000 horsepower, at a cost of $30,000.

The furniture factory of William Cyr, at Ottawa East, was destroyed by fire. The loss is placed at $8,000, insured for $7,000.

Work has been commenced on the new wagon works of T. Brayshaw, Victoria, to cost $5,000. Electricity will be used throughout.

A plant for the extraction of gas from straw to be used for fuel and power will soon be erected at Portage la Prairie, Man.

The Canadian Westinghouse Co. are equipping extensive additions to their plant in Hamilton with Chapman double ball bearings.

The Standard Chemical Co. will build a plant in Toronto, to cost $50,000. This company will also erect a plant at Delorimeter, Que.

J. Ballantine & Co., Preston, Ont., recently added to their plant a 20-ton planer, manufactured by the MacGregor-Gourlay Co., Galt.

The Colonial Engineering Co., Montreal, are installing a producer gas engine in the plant of the Frame & Hay Fence Co., Stratford.

T. C. Brewer, Woodstock, N.B., has the contract for the two new masonry piers for the Fredericton highway bridge, costing $20,000.

A mill for the manufacture of all kinds of iron pipe will be erected at Welland, Ont., in connection with the Ontario Iron & Steel Co.

The O. C. King Lumber Co., Humbolt, have sold their entire hardware, lumber and machinery business to the Saskatchewan Elevator Co.

C. Doutre is arranging for the installation of a chain of Government-owned and operated wireless stations on the British Columbia coast.

The Dominion Steel Co., N.S., suffered severely by fire recently. Their loading pier at Wabana, Nfld., was destroyed by fire. Much machinery and coal was destroyed; loss, $50,000.

The National Spring and Wire Co. are installing machinery for the manufacture of springs in their new premises at St. Catharines, Ont.

A committee is at work at Prince Albert, Sask., trying to find a method for developing power from the Saskatchewan and its tributaries.

The Sydney Foundry & Machine Co. are contemplating the removal of their works to Halifax. North Sydney is anxious to secure the industry.

The new sand lime brick plant of Schultz Bros., Brantford, which was installed by A. Berg & Son, Toronto, turns out 20,000 bricks per day.

A Buck Eye trenching machine is at work on the Moose Jaw gravity water system. It does the work of 150 men and is giving complete satisfaction.

A factory for the manufacture of steel office supplies and a grain cleaner will be erected at Portage la Prairie by Beamans & Co., Minneapolis, Minn.

The Ruud Mfg. Co., Pittsburgh, manufacturers of automatic hot water heaters, have established a Canadian branch at 155 King St. W., Toronto.

Somerville, Limited, Toronto, have placed an order with the Rohb Engineering Co., Amherst, N.S. for a 200 horsepower Robb-Armstrong Corliss engine.

The Dominion Radiator Co., Toronto, are offering for sale their yard and buildings, including foundry and machine shop on Dufferin street, Toronto.

The Canadian Brass Co., Galt, have their factory almost completed. Most of the machinery, which is of the most improved type, has been installed.

A contract has been signed by the city of Ottawa and the Ottawa and Hull Electric Power Co., by which power is supplied to the city at $15 per horsepower.

The Chignecto & Amherst Electric Power Co. will soon have their power plant at Chignecto coal mine, Maccan, N.S., in operation and transmit power to Amherst.

A firm manufacturing gas engines is desirous of obtaining a site in Barrie, Ont. They want a loan of $25,000. A sash and door factory also want to establish there.

Wm. Oliver will erect a $30,000 [illegible] factory at Lethbridge. He will also form a company and build a $14,000 plant for the manufacture of cement bricks.

MacKenzie & Mann are contemplating the erection of a large smelter and other industries at Ashbridges Bay. The initial outlay will be in the neighborhood of $30,000,000.

The Chapman Double Ball Bearing Co., Toronto, received the contract for the complete equipment of the new plant of the Standard Valve & Fitting Co., Guelph, Ont.

The Hartley Foundry Company is asking the city of Brantford for a fixed assessment. They will erect a plant to make tools and machinery fittings. They will employ 25 men.

The Cape Breton Electric Co., will erect a new power plant at North Sydney, N.S. Good progress is being made on the construction of their transmission lines to Sydney.

The T. H. Taylor Company, Chatham, Ont., have purchased the old binder twine plant from the M. J. Wilson Cordage Company, and will convert the factory into a woolen mill.

The Dennis Wire & Iron Works, London, have found it necessary to increase their facilities. They will immediately proceed with the erection of an addition to their present factory.

The Canadian Locomotive Co., Kingston, Ont., have placed an order with the Chapman Double Ball Bearing Co. for the complete equipment of their plant at Kingston with double ball bearings.

A company has been formed for building and operating a large sawmill on the north arm of the Fraser River, in British Columbia. The president of the company is R. H. McKee, Vancouver.

The permits issued at Hamilton for new industries for the first six months of 1907 aggregated $700,000. The new blast furnace and buildings of the Hamilton Steel and Iron Co., cost $300,000.

The Cascapedia Trading Co., of the States, will locate in Dalhousie, N.B., and build a saw pulp and shingle mill there if they can have a free site. The plant will cost $1,000,000, and employ 3,000 men.

Chadwick Bros. have secured the contract for brass corporation work for the city of Quebec, have just completed a contract for the city of Hamilton, and are now working on brass work for city of Toronto.

A great combination of iron and steel manufacturers is being formed in Great Britain to combat American and German competition, control the British trade and dominate the steel industry of the world.

The new molding shop of the Stevens Co., Galt, is now in full swing. The large jib crane is in its place and the firm are doing jobbing work on castings, besides making all necessary for their own use.

The new machine shop of the Northern Engineering & Supply Co., at Fort William, Ont., was opened recently. The plant is equipped with modern machinery and can handle any kind of repair or machine work.

There are rumors that a third hydro-electric power company will be formed in British Columbia, for developing power on the Cheakamus River, at the head of Howe Sound · 100,000 h.p. could be transmitted to Vancouver.

At the present time the Dunbar iron industry of Woodstock, N.S., is negotiating with the city of Fredericton, and is likely to remain there and amalgamate with the foundry firm of McFarlane, Thompson & Anderson.

Messrs. W. Knack, H. Anderson, H. H. Jackson, F. Bye and C. Howard have purchased the Hill sash and door factory at Markdale, Ont., and after installing some modern machinery will manufacture furniture of all kinds.

Swift & Co. will build an enormous packing establishment at Edmonton, to cost $1,000,000. Other factories will be built in connection to utilize the by-products. These are soap and glue factories, tanneries and button works.

The Dominion Engineering and Construction Co., Montreal, have completed the machine shop for the Canada Foundry Co., Davenport, Ont., and the new transformer building for the Canadian General Electric Co., Peterboro, Ont.

The McLaughlin Carriage Co., Oshawa, are equipping their new automobile factory with Chapman double ball bearings. This company was one of the first in Canada to install these bearings, and has had them in use over three years.

E. A. Wallberg, Montreal, is the contractor for the following: Intercolonial Railway shops, Moncton, N.B., and Halifax, N.S.; Prince Edward Island Railway shops, Charlottetown, P.E.I.; Intercolonial Railway engine house and freight yard, Pictou, N.S.

A large furniture factory is being built in Deseronto by John Dalton & Co. It is a four-storey concrete building, one hundred and fifty feet long by fifty feet wide. When completed it will employ about one hundred hands. The machinery is now being installed.

The Robertson Machinery Company have recently closed a deal by which Welland gains another substantial industry. Kischell & Co., of Toronto, are a going concern, and their amalgamation with the Robertson Machinery Co. brings to Welland a lot of new business.

Water power rights at Healey Falls, Ont., have been leased by the Ontario Government to the Northumberland-Durham Power Co. Three thousand horsepower is to be developed within two years, and the company are to begin work of development within four months after June first.

The Brantford Screw Co., Brantford, Ont., have installed a 250 horsepower gas engine run by natural gas. It was manufactured by Struthers & Wells, Warren, Pa. The Adams Wagon Co., Brantford, and the Woods Milling Co., St. George, Ont., have installed similar engines.

The J. I. Case Mfg. Co., Racine, Wis., have issued bonds, the proceeds of which will be used to build a factory in Fort William, Ont. The company have owned 192 acres of land outside the town for several years but it is only recently that their intention has been made public.

Chadwick Bros. have just installed one of the latest and most up-to-date patterns of automatic lathes from the National Acme Mfg. Co., of Cleveland, with four spindles, cross drilling and threading rolling attachment for making all kinds of brass nuts, screws, studs and bolts.

The Sherlock Manning Organ Co., of London, Ont., are erecting a new factory, which, when completed, will more than double their present output. The new building will have a floor space of 300 square feet more than the present one, making in all a total floor area of 40,000 square feet.

The Regina Machine & Iron Works Co., Regina, capitalized at $100,000, are shortly to erect a large foundry and machine works. The building, which will cost $20,000, will be fitted with a large amount of up-to-date machinery, thus enabling the company to handle practically all classes of iron, steel or machine work. The

officers of the company are: P. Cooper, E. Osborne, R. Reid, J. Reid, J. F. Embury, and J. A. Kerr, all of Regina.

The Toronto Street Railway Co. have installed in their plant, a 200-ton hydraulic wheel press, for pressing wheels on and off axles, which was made by John Bertram & Sons, Dundas, Ont. Owing to the additional work now to be done, since taking in the York Radial Railway, a heavier type of press was needed.

The Brockville Malleable Iron Company is being organized in Brockville, with local capital. The directors purpose to establish a plant capable of reducing either five tons or ten tons of castings daily. The five-ton plant complete, including $104,000 for working capital, is estimated to require $35,000, while a ten-ton plant is estimated at $50,000.

The Macdonald Co., Grand Forks, have two large contracts on hand at present for the Granby Co. They are now working at a large tank with a capacity of 100,000 gallons. The other contract is for a mammoth flue dust chamber. This flue will be 13x15 feet inside measurement and elevated 22 feet above the feed floor. 300 tons of steel will be used in the construction, which is the heaviest piece of steel work ever attempted in this country.

Municipal Undertakings.

Souris, Man., will build a hospital costing $12,000.

Welland, Ont., will spend $20,000 on improving its roads.

Montreal will spend $2,000,000 in bettering its water supply.

Chatham will improve both its water and lighting service.

The town of Truro, N.S., is installing a new fire alarm system.

Summerlea, Que., is to have a municipal electric light system.

Five Government telephone lines are being erected in Alberta.

Cardston has voted $20,000 for water works and electric lighting.

The town of Oakland, Man., is inviting tenders for a steel bridge.

Work on the $60,000 sewerage system for Selkirk, Man., is under way.

Moose Jaw is to extend its municipal electric lighting plant and system.

Tenders are called for a bridge over the Saugeen river at Teeswater, Ont

A $10,000 extension will be made to the waterworks system at Vancouver.

The city engineer of Ottawa is calling tenders for a municipal asphalt plant.

The town council of Morden, Man., is to install an electric lighting system.

Port Arthur will raise $360,000 for bridges, waterworks and street car service.

Wetaskiwin, Alta., has decided upon the construction of water and sewer works.

The Ingersoll Board of Trade is trying to secure a large steel plant for that town.

Bridgeburg, Ont., has in contemplation a sewage system that will cost about $125,000.

Goderich, Ont., is asking for $28,000 to improve the waterworks and lighting systems.

The water committee of Montreal is asking for $17,000 to extend the system to Rosemount.

The waterworks system of Chilliwack, B.C., has been taken over by a company for $34,000.

The city council of St. John, N.B., will call tenders for waterworks extension to cost $30,000.

A by-law will be voted upon in Sherbrooke, Que., for the development of power at Westbury, Ont.

Raymond, Alta., will improve its water system and install a municipal electric light system.

Brandon, Man., has voted $50,000 for a waterworks system, and $150,000 for fire equipment.

The Ottawa Electric Commission have ordered a 750 horsepower generater for the municipal plant.

Camphellford, Ont., has voted a loan of $15,000 to Jas. and Geo. Dickson for a bridge works.

Niagara Falls is to have an improved waterworks system on which $40,000 is to be expended.

Berlin has acquired interests in the Berlin & Waterloo Street Railway Co. to the extent of $76,000.

Kingston recently passed a by-law exempting two smelting companies from taxation and granting them a free site. They will smelt lead and zinc.

Sherbrooke, Que., will vote on a by-law to raise $200,000 for the purpose of developing water power.

Dunnville, Ont., has decided to grant a franchise to M. L. Perry to supply electricity to that town.

A by-law will be submitted to the town of Ingersoll for $95,000 to take over the waterworks plant.

A by-law will be submitted to the ratepayers of Niagara Falls, Ont., to raise $3,000 for a public library.

Lachine, Que., will borrow $50,000 for the purpose of improving the waterworks and sewerage services.

The town of Campbellford, Ont., is calling tenders for a water turbine, generators and transmission line.

Alymer, Ont., will vote on by-laws to purchase the waterworks, $50,000, and $60,000 for a sewage system.

Fort William will vote on bylaws to raise $94,000 for the extension of telephone, electric light and water systems.

The Ottawa Water Works Committee will install a duplicate set of pumps to give a daily capacity of 30,000 gallons.

The contract for the construction of the waterworks system at Simcoe has been let to T. M. Cullon, of Huntsville.

A by-law has been presented by the town of Newmarket, Ont., for an extension of its municipal electric lighting system.

Fort William, Ont., has voted $94,000 for the extension of the municipal waterworks, telephone and electric light systems.

The ratepayers of Estevan, Sask., will vote on a by-law to raise $82,000 for municipal electric light and waterworks systems.

The Municipal Construction Co., Regina, has secured the contract for installing a $50,000 waterworks system at Battleford, Sask.

The towns of Collingwood, Midland and Penetanguishene have applied for municipal rights to develop electricity at the Severn river.

The corporation of Ottawa may take over the Ottawa Electric Company's plant and lines and amalgamate them with the municipal lighting enterprise.

The Ottawa electric commission is making arrangements for taking over the street lighting system of the Ottawa Electric Co. $24,000 is the price offered.

The following by-laws were carried at Medicine Hat: $25,000 for waterworks extension, $20,000 for improvements to the natural gas scheme and $50,000 for fire alarms.

The Peterboro, Ont. council have decided to apply to the Hydro-Electric Power Commission to acquire water power privileges and construct the necessary works to supply cheap power.

The contract for laying sewer pipes at Fernie, B.C., has been let to Hugh Macdonald, Victoria, the contract price being $30,000. Tenders for a disposal plant will be asked for shortly.

The city of Medicine Hat is increasing the capacity of its pumping plant by 1,200,000 gallons per day. Two new pumps will be installed operated by gas engines, natural gas being used.

By-laws were carried by large majorities to assist the location in Sarnia of the Standard Chain Company, of Pittsburg, and the Jenks Dresser Company, manufacturers of iron bridges.

The Canadian General Electric Company have been awarded the contract for transformers, etc., for the municipal plant at Winnipeg, at $9,810. The Packard Electric Company, St. Catharines, obtained the contract for 100 arc lamps and cut-outs at $2,700.

Halifax intends to spend $768,500 on municipal work, as follows: Pavements, $75,000; sidewalks, $150,000; improving fire department, $70,000; water extension, $135,000; sewerage, $50,000; school houses, $95,588; street extension and various purposes, $122,500.

It is proposed that the municipalities of Orangeville and Shelburne combine to develop the buxtable water power at Hornings Mill. The amount of power which could be developed would be between 200 and 400 horse power. The cost of development has been estimated at $85,000.

Medicine Hat is installing a modern waterworks system. The Roberts Co. of Philadelphia, have the contract for a filtration plant, consisting of two 1,000,000 gallon units. The contract was also let for a huge stand-pipe with capacity of 500,000 gallons. This has already been erected.

The following by-laws were passed by the ratepayers of Fort William: To raise $68,000 for the purchase of land to be used for industrial sites; $94,000 to extend the water, light and telephone systems, distributed as follows: $36,000 for telephone, $32,000 for water, $26,000 for light; $18,000 for a fire hall and police station at Westfort; $3,750 to enlarge the central fire hall; $20,000 to purchase a site for the plant of the Imperial Steel and Wire Company.

The Winnipeg city council is in favor of adopting the Red river as a source of water supply. It is estimated that 15,000,000 gallons per day is required. The total estimated cost of the necessary work is $1,545,000. The cost of pumping and softening the water is estimated at $40, per million gallons.

Thirteen by-laws were carried at Port Arthur, Ont. They included the construction of two concrete and steel bridges, the purchase of street cars, improvements to the Current river, extension of the waterworks, erection of a police station, double tracking the street railway for seven miles, establishing of an incinerating plant, erection of a new car barns and isolation hospital and park improvements. A plebiscite on development of Dog Lake Falls carried.

Mining Notes.

Extensive additions are planned for the Granby mines, B.C.

A coal mine is being opened up at Mosher, B.C., by the C.P.R.

A valuable vein of copper has been struck near Larder Lake, Ont.

There are now twelve blast furnaces at work at the Boundary Mines, B.C.

The Nova Scotia Steel and Coal Company, Sydney, N.S., are opening a new mine.

The Boundary Smelters, B.C., are turning out copper at the rate of 4,500,000 pounds daily.

Gold, silver, iron and copper have been found on the G.T.P. at the north of Lake Superior.

P. T. Thornton, Brandon, has purchased the Wilcox coal mine at Taber, Alta., for $250,000.

The property of the Ontario Nickel Copper Company, near Sudbury, has been bought by a syndicate.

The Maritime Coal & Power Company have started operations in their new power plant at Amherst, N.S.

A mining company will be formed at Sturgeon Lake, Ont., to operate the Wyndego mine, near Kenora, Ont.

A huge reduction and refining works will shortly be erected on the property of the La Rose mine, Cobalt, Ont.

A deposit of copper claimed to be the second largest in Canada has been found north of Sault Ste. Marie.

The British Columbia Copper Company, Greenwood, B.C., have recently placed their [illegible] smelter in operation.

The Dominion Iron and Steel Company, has started a Bessemer plant which will increase its monthly output to 30,000 tons.

Coal has been found near the Yellowhead Pass, B.C., where the G.T.P. and Canadian Northern propose crossing the rockies.

Tin bearing ore with a high percentage of tin has been discovered in Lunenburg County, N.S. It will be developed by H. Peers, Halifax.

An enormous concentrator is being erected at the Blue Bell mine, near Ainsworth, B.C. Other reducing machinery is also being installed.

R. T. Anderson, of Minneapolis, has bought the lead property of J. W. Andrew, near Port Arthur. Development will commence immediately.

A very good report has been handed in about the deposits of iron ore which lie 30 miles north of Sudbury. There are enormous deposits of very rich ore. The Canadian Northern will open up the mine.

The Consolidated Mining & Smelting Company, B.C., have acquired the properties of the Phoenix Amalgamated. Active operations will at once begin and a twenty-drill air compressor will be installed.

The Nova Scotia Steel & Coal Company have awarded the contract to D. Sutherland, North Sydney, for the construction of 2¼ miles of railway, costing $50,000.

The plant for obtaing iron ore in the Nepigon district, Ont., from sand will be opened again by the North Shore Reduction Co. S. N. Smith, Minneapolis, is the promoter.

The Dominion Coal Company's shipments of June 30th broke all records, 20,000 tons being shipped to the St. Lawrence alone. The total shipments for the week amounted to 64,024 tons.

Of the fourteen blast furnaces at the Boundary smelters, twelve are now in operation, handling 5,000 or 6,000 tons of ore per day. The Dominion Copper Company have two smelters running and will soon have eight stacks in full blast.

A bituminous shale called stellarite has been found in Pictou County, N.S. It is very rich

in oil, yielding as high as 100 gallons of clarified oil to the ton. A company of New York capitalists will develop the mineral.

Owing to the shortage of ore cars the Dominion Copper Company, B.C., will build an aerial tramway from their mine to the Boundary smelter. The operations of the Granby mine have also been curtailed by the car shortage.

The mining in British Columbia has increased at a tremendous rate. The copper mines have the greatest revenue, but until recently gold had the lead. The following table shows the relation between the mining resources of British Columbia and the remaining provinces :

	British Columbia	All other Provinces
Gold	$5,579,039	$ 306,032
Silver	1,897,320	3,539,497
Copper	8,288,565	2,318,095
Lead	2,667,578	111,980
Nickel	None	8,948,934
Coal and Coke	5,458,044	14,245,032

This gives a total of $23,980,526 for British Columbia, against $31,193,876 of the other provinces. The figures are the total for 1906.

Railroad Construction.

The C.P.R. will build a round-house in Saskatoon.

The new station at Charlottetown, P.E.I., was opened recently.

The new Intercolonial station at Moncton, N.B., will cost $45,000.

The C.P.R. will build a line from Victoria Harbor to Peterboro.

The C.P.R. will build subways over Herny and Elgin Sts., Brantford.

The Grand Trunk subway at Lansdowne Ave., Toronto, will cost $53,443.

The Grand Trunk Pacific is graded for seventy miles west of Saskatoon.

Grading has been commenced on the G.T.P. east of Portage la Prairie.

Work is progressing rapidly on the G.T.P. from Saskatoon to Edmonton.

The Guelph and Goderich branch of the C.P.R. has been opened as far as Blyth.

Steps are under way for the use of electricity on the C.P.R. grades in the West.

The British Columbia Electric Railway will extend its system at Fort Langley.

Work has commenced at Fort Simpson on the Pacific and Hudson's Bay Railway.

The C.P.R. will spend $257,000 in Saskatoon, Man. The new station will cost $50,000.

The C.P.R. will call for tenders for a steel bridge at Lethbridge, to cost $1,000,000.

The Canadian Pacific are double-tracking their line between Fort William and Winnipeg.

Work has commenced on the construction of the Kingston, Ottawa Railway, at Rideau.

The Scott Machine Co., London, are constructing two test boring machines for the C.P.R.

The Strathcona-Alberta Radial Tramway Co. are anxious to operate a street railway system.

The Halifax & South Western Railway have let the contract for a steel bridge near Halifax.

The Hamilton Steel and Iron Co. have commenced making railroad spikes from basic steel bars.

The C.P.R. will erect a power house in connection with their new hotel at Victoria to cost $40,000.

The Quebec, Montreal and Southern Railway has been purchased by the Delaware & Hudson R.R.R.

Vancouver is to be connected by trolley with Tacoma. Slone & Webster have bought the franchise.

The C.P.R. are reducing the grades in the Crow's Nest Pass and otherwise improving the roadbed.

The C.P.R. will replace the wooden trestle over the Rideau River at Merrickvelle with a steel bridge.

Plans are out for a new $40,000 station and a twenty one stall round-house for Estevan, Sask., for the C.P.R.

The Canadian Northern are looking forward to the completion of the Brandon-Regina line in the near future.

The Canadian Northern will run a branch from Fernie up the Elk River. This will open up some good coal areas.

Operations have commenced on the erection of the new car and erecting shops of the Prince Edward Island Railway.

The contract for the construction of a three hundred thousand dollar pier at Vancouver has been awarded by the C.P.R.

Thomas Merrill, Duluth, will build a logging railway 16 miles long, through his lumber claims in British Columbia.

It is understood in railway circles that a universal signal system will be adopted on all American and Canadian roads.

The new owners of the Woodstock, Thames Valley and Ingersoll Railway will construct the line between Ingersoll and Woodstock.

The work of electrifying the Sarnia tunnel is progressing rapidly. The machinery is on the ground and will soon be installed.

Plans are under way for the erection of a union station at Portage la Prairie by the G.T.P. and Canadian Northern Railways.

The contract for the construction of 50 miles of the C.P.R. on the Shedo extension has been awarded to J. G. Hargrave & Co., Winnipeg.

The C.P.R. will construct fifty giant locomotives for the use on the mountain division. They will have a draw bar pull of 40,000 pounds.

It is stated that the Canadian Northern will use electricity developed by the Slave Lake Power Co., to operate its Vancouver-Seattle line.

The contract for 65,000 tons of steel rails for the National Transcontinental Railway has been awarded to the Dominion Iron & Steel Co., Sydney, N.S.

Operations are soon to be commenced on the electric line from Bellingham, Wash., to British Columbia. E. W. Purdy, Bellingham, is one of the directors.

A large roundhouse is being constructed at Smith's Falls, Ont. by the C.P.R. It will have capacity for 22 of the largest engines that the company have.

The Canadian Northern Railway is to erect its new Winnipeg shops in Fort Rouge. The total cost of the buildings will be $76,000. The arebitect is Samuel Brown.

The contracts for the five steel bridges on eastern Quebec section of the Natianal Transcontinental Railway have been awarded to the Dominion Bridge Co., Montreal.

Work is going on for the relaying of the Grand Trunk double tracks between Montreal and Toronto with hundred pound rails, the old eighty pound steel rails being taken up. This will make the heaviest rails over such a section of track in Canada.

The two chief projects in railway construction this season in British Columbia will be the new electric line from New Westminster to Eburne. The other will be started as soon as contracts are let. Both lines will be operated by the B.C. Electric Railway Co.

The Northern Empire Railroad Co. is the latest aggregation of Americana organized for the purpose of building a railroad into Canada. It will cross the international boundary near Cardston, Alberta, and from thence will run north to Fort McMurray on the Athabasca River.

The contract for the Eburne-Westminster branch of the C.P.R. has been awarded to J. B. Price, Vancouver. The British Columbia Electric Railway Co. will electrify and operate the line. This company will also take over the branch from Westminster Junction to New Westminster.

The Government has approved of contracts for Intercolonial locomotives and rolling stock to the amount of about $1,000,000. The locomotives are chiefly heavy freighters. A large order for cars was divided between the Crossen Car Co., of Cobourg, Ont., and Rhodes, Curry & Co., of Amhearst.

In the near future the C.P.R. will operate its trains from Fort William west, for about 30 miles, and also over the heavy grades in the mountains, by electric moguls. For the Fort William grade the power will be drawn from Kakabeka Falls, while the Bow, the Kicking Horse, the Beaver, the Illecillewalt, the Eagle and the Fraser will furnish ample power for the mountains.

Companies Incorporated.

The Hub Spoke and Bent Goods Co., of Sarnia, have changed their name to Loughead, Limited.

The Argenteuil Lumber Co., Morin Flats, Que.; capital, $30,000 ; to deal in lumber and construct and maintain wharves, piers, etc.

Buffalo Larder Gold Mines, Limited, Toronto ; capital, $2,000,000. Provisional directors : C. S. MacInnis, C. C. Robinson, all of Toronto.

The Northern Reduction Co., Toronto, capital, [illegible],000 ; to mine, mill and reduce ores. Incorporators : W. C. Mackay, T. D. Byers, A. N. Morine, T. Pottage, all of Toronto.

Morden, Limited, Brandon, Manitoba ; capital, $50,000 ; to manufacture gas and electric fixtures. Provisional directors : M. W. Morden, J. Watson and J. B. Nobel, all of Brandon.

The Jones Safety Device Co., Hamilton ; capital, $50,000 ; to do a machinery business in Hamilton. Incorporators : C. Readman, Grace Hewson, Florence Philips, all of Toronto.

The Elgin Cobalt Mining Co., St. Thomas, Ont. ; capital, $200,000 ; to carry on mining, milling and reduction of ores. Directors : J. H. Courtenay, W. H. King and J. T. Utter, all of St. Thomas.

The Ridgetown Canning Co., Ridgetown, Ont.; capital, $100,000 ; to carry on a fruit and vegetable canning business. Provisional directors : C. B. Kenleyside, B. V. Hole, G. E. Coleman, London, Ont.

Canadian Lithographic Stone Co., Montreal ; capital, $500,000 ; to carry on a mining, milling and reduction business. Incorporators : R. B. Hutcheson, F. W. Hibbard, W. J. Ross, all of Westmount, Que.

Cobalt Confederation Mines, Limited ; capital, $3,000,000, Cobalt ; to carry on the business of mining, milling, reduction and development. Provisional directors : J. S. Bosquet, M. McLeod, R. Herron, F. C. Powell and H. Hortman, all of Cobalt.

Missisquoi Marble Co., Missisquoi, Que., capital $500,000 ; to deal in marble, tile brick and carry on the business of house decorators. Directors : J. T. Shearer, R. J. Dale, S. H. Ewing, S. Carsley, W. Mann and H. Timmis, all of Montreal.

Dillons, Limited, Montreal, capital $49,000 ; to manufacture and deal in drugs, chemicals and dye-stuffs. Directors : G. A. Dillon, R. P. Dillon, R. Taschereau, S. Dore and R. Genest, all of Montreal.

The Hydro-Electric Construction Co., Toronto; capital, $50,000 ; contractors, hydraulic and electrical engineers. Provisional directors : A. Keith, A. G. Lawrence and W. R. Wadsworth, all of Toronto.

The Red Jack Mining Co., Midland ; capital, $500,000 ; to carry on the operations of a mining, milling reduction and development company. Provisional directors : J. S. McDonald, A. B. Thompson and T. J. Wilson.

Montreal Gold and Silver Mining Co., Cobalt ; capital, $10,000 ; to carry on all branches of mining, milling reduction and development. Provisional directors : O. Baker, W. J. Sutherland and J. C. Armstrong, all of Cobalt.

The Electric Smelters, Ottawa ; capital, $18,000 ; to deal in electric smelters and supplies. Directors : J. H. Reid, Cornwall ; G. P. Borphy, E. D. Lafleur, J. C. Scott, all of Ottawa, and S. L. Tingley, Providence, U.S.

The Galetta Electric Power and Milling Co. ; capital, $100,000 ; head office, Arnprior, Ont.; to develop electrical energy. Provisional directors: T. Moran, M. Sullivan, both of Arnprior, and J. Brennan, of Sand Point, Ont.

The Ontario Metal Novelty Manufacturing Co.; capital, $100,000 ; head office, Toronto; to manufacture metal novelties, machine tools, dies, etc. Provisional directors : E. Currie, M. Campbell, J. S. Woodhouse, all of Toronto.

An Ontario license has been granted to John S. Metcalfe Co., Illinois, to construct elevators and manufacture all kinds of machinery. R. S. McFarlane, Midland, Ont., will be the company's attorney, with a capital of $50,000.

A company to be known as Pressed Bricks, Limited, has been formed in Edmonton for the manufacture of pressed bricks by the Berg process. The officers are : President, D. R. Fraser ; vice-president, C. May ; directors, A. Brown, C. Gallagher, J. H. Gariepy, A. J. Manson and J. Macdonald ; secretary-treasurer, H. J. Helliwell, all of Edmonton.

Building Notes.

Swift, Copland & Co., Montreal, are building a factory in Montreal.

The Manitoba Government will erect a telephone exchange at Brandon.

A high school will be erected at Smith's Falls, Ont., to cost $45,000.

The Diamond Glass Co., Toronto, will build an elevator costing $20,000.

Tenders are invited for the construction of an armory at Walkerton, Ont.

The C.P.R. is asking for tenders for the erection of the station at Calgary.

The Royal Bank of Canada will erect a building in Toronto, costing $200,000.

The Bank of Montreal will erect a branch at Portage la Prairie to cost $55,000.

The Adams Wagon Co. will erect a brick warehouse at Brantford costing $8,000.

An addition is to be made to the King Edward Hotel, Toronto, costing $500,000.

The congregation of Knox Church, Galt, are to erect a schoolhouse costing $25,000.

St. Anne's Church congregation, Toronto, is to erect a brick edifice to cost $30,000.

A company is being formed for the purpose of erecting a $75,000 hotel at Lethbridge.

Queen's University, Kingston, Ont., will erect a biological building, to cost $35,756.

$12.00 Per Annum Per Horse-Power

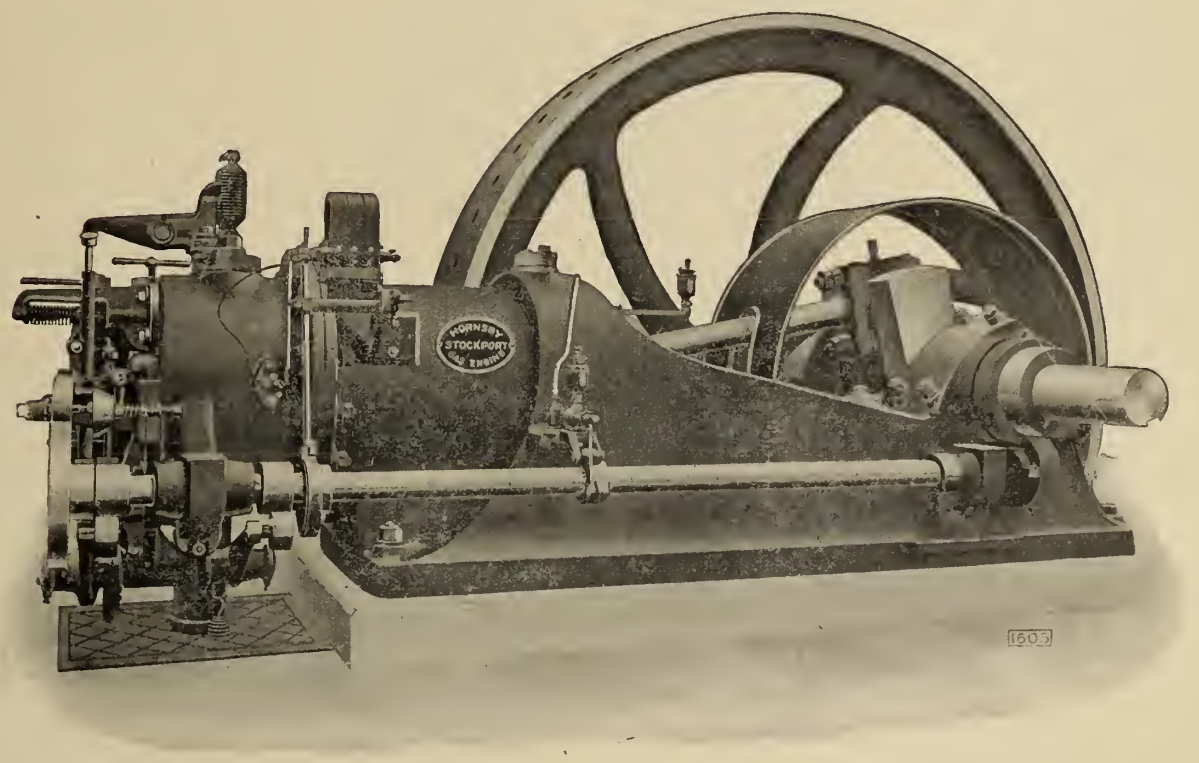
COLONIAL ENGINEERING COMPANY, Limited

222 and 224 ST. JAMES ST., - MONTREAL

SOLE CANADIAN AGENTS FOR

HORNSBY-STOCKPORT GAS ENGINES

(BUILT IN ENGLAND.)



150 H.P. Hornsby-Stockport Gas Engine.

NO odor. NO danger. NO pressure. NO smoke stack. NO steam boilers.

NO boiler feed pumps. NO feed water heaters, and NO complicated auxiliary apparatus.

IT generates its own gas in exact proportion to a varying load.

IT produces its own impulse exactly when required and not otherwise.

IT consumes, therefore, only an amount of fuel exactly in proportion to the actual power developed.

IT lubricates its own parts, pumps its own water, attends entirely to its own economy and gives absolute value for every ounce of fuel consumed.

Large equipments now being installed for several of the most representative manufacturing companies in the Dominion.

It is stated that a Toronto syndicate will erect a large hotel on the Caer Howell site, Toronto, to cost $300,000.

The building permits issued in Regina for June include: R. H. Williams' block, $40,000, and Af W. Smith's block, $35,000.

A modern apartment house will be erected at Vancouver costing $350,000. Champion & Pound are the local representatives of the company.

Among the buildings being erected at Regina are: F. N. Darke, business block to cost $110,000; Masonic Temple, $50,000; J. W. Smith, [illegible] & Brown, block, $35,000.

A syndicate has been organized, including Messrs. Campion and Pound to erect a ten-storey apartment house in Vancouver, to cost $250,000.

Work has been started by the Mortimer Company, Ottawa, on a $25,000 addition to its premises. The addition is to be used for the printing rooms.

A new one hundred barrel flour mill will be erected in Rosthern, Sask. this summer by the Rosthern Flour Mills Company, costing in the neighborhood of $20,000.

The Dominion Radiator Works will build a large chimney in connection with their works in Toronto. The stack will be 125 feet high, contain 25,000 bricks and cost $20,000.

An enormous rink will be erected at Halifax, N.S. to cost $55,000. The Commercial Cable Co. will build a $9,000 cable tank on their premises. The Silliker Co. will build an $8,000 paint shop.

The Great Northern Railway will erect a new station at Brandon to cost $30,000. The Brandon Construction Company are the contractors. A new winter fair and stock pavilion will also be erected costing $24,500.

The Lands Produce & Cold Storage Company are building a large cold storage plant at St. John, N.B., to cost $60,000. Apple factories will be erected in the Annapolis Valley and a canning factory at Kentville.

The following buildings are being erected at Saskatoon: The National Trust Co., $5,000; Canadian Bank of Commerce, $65,000; the Great West Furniture Co., $50,000; the Sutherland Block, $10,000; the Alexandra School, $35,000.

The following buildings are being put up in Hamilton: New armories, costing $250,000; Herkimer Baptist church, to cost $23,000; Home for [illegible]; Isolation Hospital, $15,000; a new building in connection with the Home for Consumptives to cost $10,000.

Among the more important buildings being erected at Prince Albert, Sask., are: McKay & Adams' brick block, $30,000; P. D. Tyerman, hotel, $25,000; J. Sanderson, brick block, $50,000, and Presbyterian Church, $45,000.

The Colonial Investment and Loan Company will erect a skyscraper on Yonge St., Toronto. The plans call for a building of steel, brick and terra cotta, ten stories high, to cost about $150,000, exclusive of the cost of the land.

Statistics gathered from 37 towns throughout the west show that buildings actually under way therein amount to $22,500,000, exclusive of Winnipeg. In Edmonton alone $6,000,000 will be expended in new structures. This wonderful development, great as it is, would be one-third more were it not for the prohibitive rates charged for lumber. Wages are uniformly high.

Among the buildings being erected at Prince Albert are the following: Sanderson & Knox block, $55,000; Pollock block, $10,000; Moore block, $40,000; Prince Albert Times block, $5,000; G. W. Baker, residence, $12,000; high school, $100,000; fire hall, $10,000; Baker & Eaton block, $40,000; R. C. Church, $70,000; S. J. Donaldson, residence, $5,000 and A. MacDonald, residence, $8,000.

* * *

To Build Ornamental Iron Works Plant.

The Canadian Ornamental Iron Works, 55 Yonge St. Arcade, Toronto, are preparing plans for a new plant for the manufacture of ornamental iron work, including iron fence, stairs, etc.

* * *

Starts Operations.

The new factory of the Gilson Manufacturing Co., Limited, at Guelph, Ont., Canada, is now ready to start operations. The plant is modern and is equipped in an up-to-date manner.

* * *

Greeys Again in Running Order.

Fire did damage to the plant of Wm. & J. G. Greey, Toronto, recently, but repairs have now been made and everything is in running order again.

Goldie-McCulloch to Make Producer Gas Plants.

The Goldie-McCullough Co., Galt, Ont., are installing machinery for the manufacture of gas engines. At first engines of 160 horsepower will be built, these will be given a thorough test before other classes are constructed. Producer gas plants will be manufactured in connection with the engines.

* * *

Fairbanks' Offices Renovated

The head offices of the Canadian Fairbanks Co., Montreal, have been renovated to very good effect. The wood finishings are done in stained chestnut, which give it a very home-like appearance. The flat throughout is illuminated by the most improved system of enclosed arc lamps.

* * *

Hamilton Tool and Optical Reorganize.

The name of The Hamilton Tool & Optical Company, Limited, has been changed to "Hamilton Tool Company, Limited," and the office and factory will shortly be removed from 80 Murray St. to much larger premises on the corner of Catharine and Barton Sts., where in future the business of the company will be carried on.

* * *

Extension to Moose Jaw's Electrical Plant.

The following extensions are proposed by the city council of Moosejaw to the municipal electrical plant: two boilers and a smoke stack; a boiler house with a capacity of 2,000 horsepower in boilers. One year from now it is proposed to add two more boilers, a 500 kilowatt steam turbine, together with the necessary equipment.

The city council are considering the introduction of a by-law for the raising of debentures of $90,000.

* * *

Pintsch Producer Just Installed.

The installation of a 100 h.p. producer gas plant and engine, has just been completed by the Economic Power, Light & Heat Supply Co., Toronto, for the Christie, Brown & Co., Toronto. The installation consists of a Pintsch producer and a National gas engine. The fuel used in the producer is gas work's coke, which has proved very satisfactory fuel. The plant has been operated, and works very well indeed. Some figures regarding the cost of operating the plant will be given later.

* * *

Installation of Producer Gas Plants.

The Colonial Engineering Co., Montreal, are under contract to install two 100 h.p. Hornsby-Stockport suction gas plants and engines for Ames Holden, Limited, Montreal; one 100 h.p. equipment for Lamontague, Limited, Montreal; one 100 h.p. equipment for the Empire Manufacturing Co., London; a 200 h.p. municipal lighting plant equipment for Chatham; and also other smaller plants.

This company are doing well considering that they have been in business such a short time.

* * *

A Large Pumping Engine.

Mather & Platt, Limited, Manchester, Eng., of whom Drummond, McCall & Co., Montreal, are Canadian representatives, have been awarded an order from the Montreal Water & Power Co. for a large turbine pumping engine, to be installed at the St. Gabriel pumping station next January. This new engine is claimed to be the largest pumping engine in Canada, if not in America. Its capacity is 15,000,000 gallons per day with a pressure of 175 pounds, or a head of 406 feet. The pump is driven by one of Mather & Platt's own motors, the entire pumping apparatus will be arranged on one bed of plate.

* * *

French Company Open Offices in Philadelphia.

Ph. Bouvillain & E. Ronuray, which firm exhibited their universal system of machine moulding at the Philadelphia convention of the American Foundrymen's Association, have opened offices at 1315 Race St., Philadelphia, from where they will handle their United States and Canadian business. They have put a number of machines in operation at this address on a considerable variety of pattern plates. This they think is the best illustration of what can be made on molding machines.

MANUFACTURERS AND MANUFACTURERS' AGENTS.

It will pay you to watch our condensed column each month. There are many money-making propositions brought to your attention here. You may find just what you are looking for.

RATES

One insertion—25c. for 20 words; 1c. a word for each additional word.

Yearly rate—$2.50 for twenty words or less, 10c a word for each additional word.

The above does not apply to notices under the head of "Machinery Wanted." These notices are inserted free for subscribers.

BUSINESS CHANCES.

WANTED—A large and well-equipped factory to build meat slicers; large quantities desired. Write for particulars to Wolf, Sayer & Heller, Montreal. [8]

A GOOD cash paying electric wiring business; a small capital only required; selling out owing to ill health. For particulars apply to Box 31, CANADIAN MACHINERY, Toronto. [8]

MACHINISTS—$5,000 buys at par stock in established manufacturing company, western city; salesmen, machinists, blacksmiths, accountants; here's a chance; assets exceed two hundred thousand and company solid financially; write us if interested. Locators, Winnipeg.

FOR SALE.

BELTING, RUBBER, CANVAS AND LEATHER, Hose, Packing, Blacksmith's and Mill Supplies at lowest prices. N. Smith, 138 York Street, Toronto. (2tf)

MANUFACTURERS' AGENTS WANTED.

SHEFFIELD manufacturers of tool steel, spring steel, section bars, etc., as advertised on page 16, wish to correspond with reliable Canadian firms with view to sole agencies in certain territories. Address "Newhall," care CANADIAN MACHINERY, 88 Fleet Street, London, Eng.

SITUATION VACANT.

WANTED—Young man well experienced in machinery supply business able to sell and knowing thoroughly all requirements of the trade. Salary, commission and share of profits. Apply Box 32, CANADIAN MACHINERY, Toronto.

SITUATIONS WANTED.

ADVERTISER, shortly emigrating, seeks position as correspondence clerk and accountant. Well up in all details of engineering and allied business; ledger, balancing, shorthand and typewriting; excellent references. Lister, Ipswich Road, Ardleigh, Colchester, Eng.

DRAUGHTSMAN mechanical, 29; situation required in Montreal, immediately; constructional and general engineering experience; Lancashire and Cornish boilers, riveted ironwork, cast ironwork; getting out quantities; shorthand. "Draughtsman," 30 Church Street, Lozell's, Birmingham, Eng. [8]

ENGINEER, Scotchman (33), single, all round millwright and draughtsman; been superintending constructional work and 9 years works manager of iron foundries; excellent references; open for anything in line; any part of Canada. Box 330, CANADIAN MACHINERY, 88 Fleet St. E.C., London, Eng. [7]

YOUNG man representing five large American manufacturers desires to make connection with a Canadian machine supply house or hardware firm wishing to open a mill supply department. Box 24M, CANADIAN MACHINERY, Montreal. [7]

AGENTS WANTED.

A Firm of Chemical Engineers

are requiring first-class agents in the large cities of Canada. Apply to W. J. Fraser & Co., Ltd., Chemical Engineers, 98 Commercial Road East, London, England. [11]

The easiest way to obtain or sell second-hand machinery is to place a "want" ad. in Canadian Machinery.

The Canadian Turbine Water Wheel

Searching comparisons with other turbines are invited.
We are making them every day and have still to find our equal on any class of work.
Write us now for information; the season is getting late.

"Best" Dry Cells

For your Ignition in

Automobile
Motor Boat
Gas Engines

The kind the largest Telephone Company in Canada is using to-day, because they give the longest service.

Ask your dealer for them, or

The Berlin Electrical Mfg. Co.,
Limited
474 King Street West, TORONTO

"Economo" Emery Wheel Dresser

A Substitute for the Black Diamond

"ECONOMO"

ECONOMO COMBINATION

PRICE: Economo, $4.00 each; Economo Combination, $4.50 each.

Will true or shape any wheel except the very hardest and carborundum. The most efficient Roughing Dresser on the market—never gets dull from use.

Made of an abrasive nearly as hard as the Black Diamond. The Combination dresser is the roughing dresser placed in the "handle end" of the "Regular." It is made with corrugated tool steel discs and excels in wear and efficiency any dresser heretofore made. These tools are guaranteed satisfactory or money refunded. Sent on 10 day trial.

INTERNATIONAL SPECIALTY CO.
363 Holden Ave. DETROIT, MICH.

Persons addressing advertisers will kindly mention having seen their advertisement in this paper.

We should have your business.

If prompt delivery, reasonable prices and best of workmanship appeal to you, we should have your pattern orders.

An intelligent Engineer uses nothing but the **GENUINE PENBERTHY INJECTOR.** He has had experience with just-as-good kind before.

DO YOU USE PLUMBAGO IN YOUR FOUNDRY?

If you do, we would like to submit a sample of our

Columbia Dry Sand and Loam Facing

which we are now marketing, and which will cost you from 200 to 300 per cent less than your Plumbago, yet gives as good, if not better, results.

It can be used on the heaviest kinds of cores, dry sand, loam and skin dry work. The sample will cost you nothing, as we know that a trial will convince you of its economy and plainly show its many advantages; therefore we will be willing to stand this expense, if you will give it a fair test.

TOOL ROOM ECONOMY :—

The Use of Diamo-Carbo Emery Wheel Dressers.

The ***Diamo-Carbo Dresser*** is the only satisfactory substitute for the black diamomd. Permits you to true and shape your wheels just the same as with the more expensive device, and is adapted for use on all tool grinding wheels. The hardest abrasive known; wears indefinitely; and cannot get lost or broken and will not injure the edges of the most delicate wheels.

Made in three lengths: 8", 10" and 12" respectively.

Prices: $3.00, $3.50 and $4.00

Tell us which length is best suited for your needs, and let us send a Dresser on ten days' trial. Booklet and testimonials for the asking.

WE CONTEND THAT

The Busy Man's Magazine

IS the best publication in the magazine line. But don't take our word for it. Read the unsolicited opinions of its subscribers—

"I consider The Busy Man's Magazine the best I have yet come in contact with." Henry Wilson, Toronto.

"It is the most interesting publication of its kind I have ever subscribed to." G. F. Haworth, Toronto.

"There is no better printed in the world to-day for busy men." B. T. Petch, Regina, Sask.

"Your magazine is the best I have ever had the privilege of perusing." S. W. Wynn, Yorkton.

"We would not like to miss the future copies of The Busy Man's Magazine." Ingersoll Packing Co., Ingersoll.

"I am pleased to say that each number is becoming more valuable and interesting." A. B. Musselman, Berlin.

"I am more than pleased with my investment in The Busy Man's Magazine, believing it to be the best magazine I have had the pleasure of perusing." A. B. Burrell, Amigari.

"I have been delighted with the Busy Man's Magazine. The articles are well chosen, are concise and ably written. For a busy man I know of no other magazine that will compare with it." Geo. Anderson, Toronto.

"The articles in The Busy Man's Magazine are just what we want, short and so well written that a busy man can afford time to read them and feel benefited for the short time given to each article." Wm Thoburn, Almonte.

We wish to give you further proof of the value of the ***BUSY MAN'S.*** Send us a postcard, giving your address and we will send you a sample copy.

Bear in mind every timely, interesting and instructive article appearing in any of the current magazines and periodicals appears also in the ***BUSY MAN'S***—a hundred magazines for the price of one.

STARRETT TOOLS

ARE THE STANDARD

FOR ACCURACY, WORKMANSHIP, DESIGN AND FINISH

Improved Levels for Testing Shafting, etc.

In addition to the regular parallel vial, the bases have a cross level which enables one to place or hold the base on a shaft level in its cross section, not canted sidewise; for the shape of a level glass is such that, though true as adjusted on a flat surface, it will not be reliable when canted sidewise. Hence the value of the cross level, not only to test the truth of shafting, but other surfaces which tend to throw the level base into a canting position.

The base of this level has our improved concaved groove running through the length of its base, leaving a flat margin each side, which improves its seat for flat work, while forming an absolutely true and reliable seat for shafting, etc., and it is better than a V groove. Made in 6, 8, 12 and 18 in. sizes with plain vials and with ground and graduated vials.

ARMSTRONG BROS. TOOL CO., 106 N. FRANCISCO AVE. CHICAGO, U.S.A.

"THE TOOL HOLDER PEOPLE"

RUGGLES Perfection Flue Cleaner

Made on strictly mechanical lines of the best material. Self adjusting, light, strong and simple. Heads or ends are drop forged steel, undeniably the strongest Flue Cleaner made, though no screws or rivets are used in its construction. The Knives are so made that they are always sharp, and like a plane have the tendency to work deeper, and on account of their long shearing cut, it is impossible to tell when passing through welded flues of the worst character, as the design of the Cutter is such that it is always in direct contact with the metal of the flue.

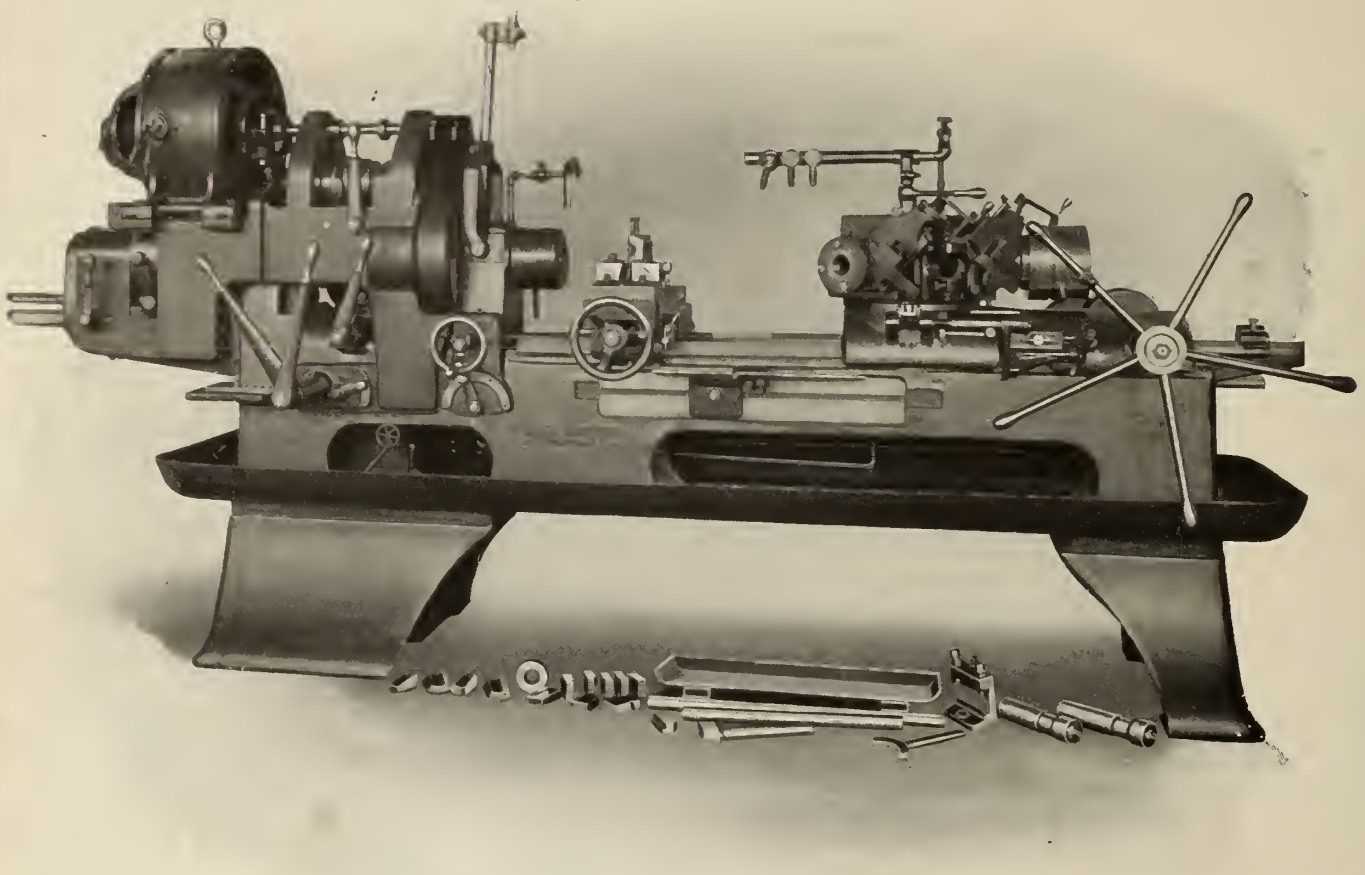
TURRET LATHES

FIVE SIZES, 5/8 x 4½-inch, 1 x 10-inch, 1½ x 18-inch, 2 x 26-inch, 3 x 36-inch.
The Turret Lathe is indispensable in the shop where duplicate pieces are produced and greatly increases production at a much lower cost.
WRITE FOR NEW CATALOGUE "TURRET LATHES."



3 x 36-inch Pratt & Whitney Turret Lathe, driven by 5 h.p. motor.

The motor drives through a speed-box which, with the double friction back-gears, affords a wide range of speeds.

Cross and longitudinal power feeds are positive geared, reversible, and have automatic stops in either direction.

The cross slide permits the use of larger forming tools than can be held in a turret and makes possible the use of three turret tools at one time.

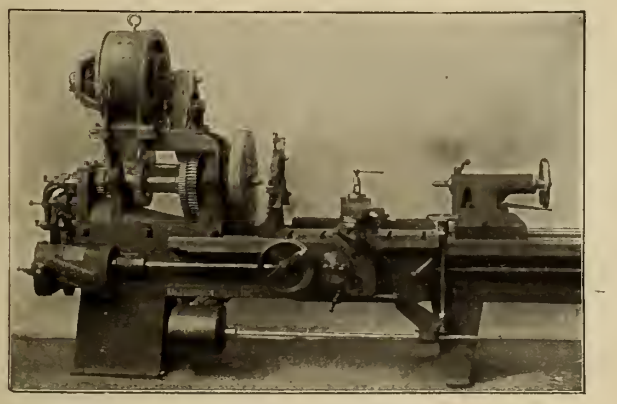
Westinghouse Motor-Drive

For Machine Tools.



Westinghouse Motor Driving Johnson, Jr., Co.'s Lathe.

Electric drive allows of great flexibility in arrangement of tools and in making additions to the plant. On account of its easy regulation and control, it always keeps the tool at its maximum capacity, and thus makes both tool and operator more valuable. Reliable data shows an increase of more than 25 per cent. in the producing capacity of electrically driven shops, as compared with mechanical drive.

The Machine

The Acme is a high grade special tool designed and adapted to eliminate all waste of time in the manufacture of **Duplicate Parts** from the bar.

It does several things at one time—and does them all well.

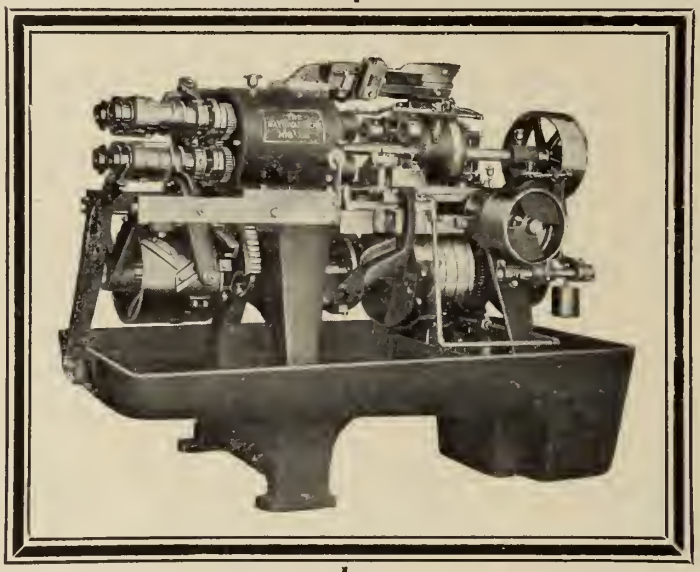
The Product

The Acme way is the most modern method of screw making. The machine is equally well adapted for making all classes of **Duplicate Parts** from the bar.

Quality—As good as the best

Quantity—Far greater than the next best.

The Acme Automatic Multiple Spindle Screw Machine



Our Claim

The Acme is the most economical machine tool on the market for the manufacture of Duplicate Parts from the bar.

The Basis of Our Claim

The constant operation in our Product Department during the past ten years of a large and increasing number of Acmes on all classes of screw machine work.

The Method

The Acme operates on four bars at a time.

It performs eight or more operations simultaneously.

It engages all the tools (one set only) at one and the same time.

Our new descriptive booklet will be mailed on request.

The National-Acme Mfg. Co.

Cleveland, Ohio

Branch Offices

New York Boston Chicago

General Foreign Representatives

Alfred H. Schutte Schuchardt & Schutte

Some Things to Consider

The Acme completes the piece in the length of time required for the longest single operation.

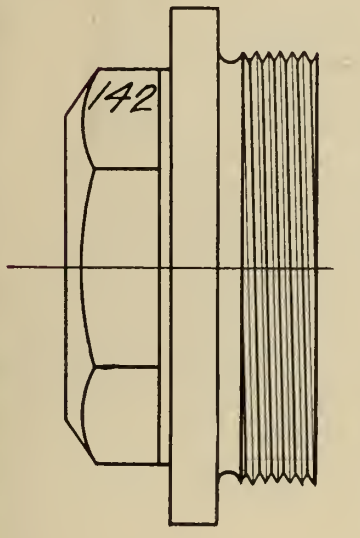
It costs no more to operate than any other screw machine.

It occupies no more floor space.

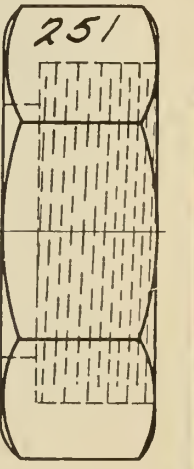
You get quality as well as quantity from the "Cleveland"---two essentials in any machine manufacturing plant---

Let us prove the superiority of the Cleveland on your work.

"The Pre-eminence of the CLEVELAND is indisputable"



Piece No. 142.---Material, Brass Casting, made on a 2¾-inch Cleveland Automatic Turret Machine; drawing full size; time of all operations for completing this piece 4 minutes; actual cost of labor from 4 to 5 mills.



Piece No. 251.---Material, Brass Casting, using our Tilting Magazine Attachment on a 2-inch 3-Hole Cleveland Automatic Turret Machine; drawing full size; output per hour 35; this means all operations for completing this piece; actual cost of labor from 2 to 2½ mills for each piece. Send along samples or drawings. We guarantee our outputs. One man can operate from 4 to 6 machines.

AS WE HAVE NO CANADIAN REPRESENTATIVE, WE SOLICIT CORRESPONDENCE AND ORDERS DIRECT.

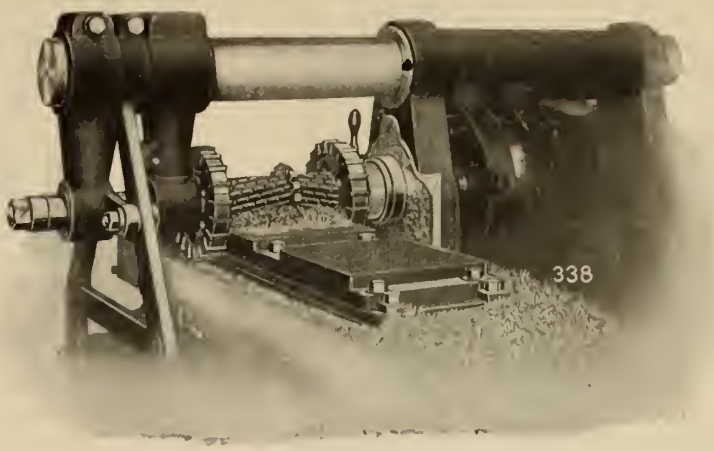
Planing | **Milling**
105¼ Minutes | **51¼ Minutes**

No. 4 Plain "Cincinnati" Motor-Driven Miller.



These are grey iron castings, 10¼" wide 14" long. The operation shown takes a cut $\frac{3}{16}$" deep across the top surface and the two edges, and also cuts the $\frac{5}{8}$XI" slot from the solid with cutters 8", 3½" and 5¾" diameter, all at one time, at a table travel of 4.2" per minute. The time on this operation, including chucking, is 15.6 minutes. The average time for milling one piece complete is 51½ minutes Former planing time, 105¼ minutes. ***The miller saves more than half the planer time.***

Are you using Cincinnati Millers? **We are Milling Specialists.**

THE CINCINNATI MILLING MACHINE COMPANY, Cincinnati, Ohio, U. S. A.

Canada Agent: H. W. PETRIE, Toronto and Montreal.

POTTER & JOHNSTON

MANUFACTURING AUTOMATICS

will machine your duplicate parts from all kinds of castings, forgings and the bar with extreme accuracy and more economically than upon any other tools in the market.

Catalogue showing interesting specimens of parts finished on these tools free upon request.

LIFTING MAGNETS

After several years of quiet preparation we announce our readiness to fill orders for Lifting Magnets.

Cutler-Hammer Lifting Magnets are designed by engineers who for years have devoted themselves to problems involving electric and magnetic control. They possess **distinct advantages** not to be found in any other Magnet now on the market.

Under rigid service tests the records established by these Magnets have been so far in advance of anything previously accomplished that we are prepared to accept orders under the following:

"Three-Way" Guarantee

1.—AS TO WEIGHT: The Magnet we will build for you will be as light as is consistent with proper design and its weight will be guaranteed **not to exceed** that of any comparable Magnet.

2.—AS TO EFFICIENCY: The lifting capacity of our Magnet will be guaranteed to **exceed** that of any comparable Magnet now in use.

3.—AS TO OPERATING COST: The operating cost per ton of material moved will be guaranteed to be **less** with our Magnet than with any comparable Magnet.

Send for Illustrated Booklet. When writing, state size of Magnet desired and nature of material to be handled.

CARBORUNDUM
NIAGARA FALLS

LET our experts prescribe for your grinding needs.

Grinding is a scientific operation these days.

Manufacturers rightly demand, not merely a grinding wheel, but the most economical grinding wheel that can be produced.

And the Carborundum Company's trained experts are here to supply the demand.

There are something like 200,000 different sizes and grits and styles of wheel regularly made, and a lot more that are made to order for special purposes—

And each individual wheel does some one thing better than any other wheel.

If you will write us your grinding needs we will be glad to tell you the wheel best suited to your particular requirements.

Let us send you the Carborundum book.

The Carborundum Company
Niagara Falls, N.Y.

ALUNDUM

The New Synonym For Uniformity,

Durability and Economy—
in Grinding Wheels.

ALUNDUM TRADE MARK NORTON REGISTERED PATENTED ELECTRIC PROCESS

These elements are found in **Norton Grinding Wheels** made of Alundum, the hardest, sharpest and most durable abrasive.

Grinding Wheels made of this material must naturally be more uniform and even throughout than when made of natural or artificial abrasives which vary in purity and uniformity.

An essential quality in an abrasive is correct temper, *i.e.*, strength of the grain and the character of its fracture. An Alundum grain is exceptionally sharp, and when it "breaks down" it always presents a fresh, keen-cutting edge. Thus the maximum cutting efficiency of **Norton Grinding Wheels** made of Alundum is always maintained and with the right grade and grain you can secure accurate and uniform work.

No matter what kind of grinding you do, we can supply the wheel for the work. All sizes, shapes and grits.

The Milling Machine Vise

Some suggestions for the use of the Milling Machine Vise on ordinary work and work requiring special arrangement of jaws.

By JOHN EDGAR.

In the July number under the above title, the various kinds of vises that are used on the milling machine were described; methods were also given by which the truth of the jaws might be tested for accurate work. In this article it is the purpose to give some examples of work and a few suggestions for the use of the vise, both on ordinary work and work that requires some special arrangement of the jaws. What may be said in this article applies to the flat vise in particular, but in most cases the methods described may be used in connection with the other vises, either without variation or with some slight change which will in each case become obvious.

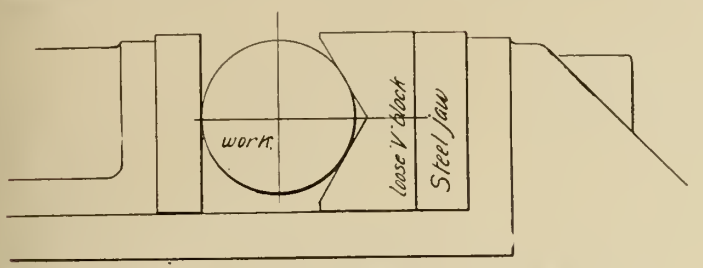

Fig. 1.—Use of "V" Block for Holding Round Work in the Vise.

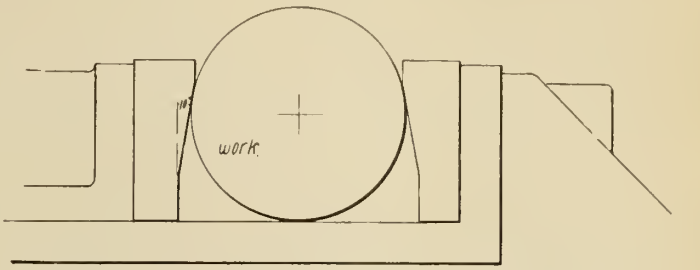

Fig. 2.—Special Jaws Fitted to Vise for Holding Round and Rectangular Work.

Holding Rectangular Work.

In holding plane rectangular work in the vise the only precaution necessary is to see that it is well seated in the bottom of the stationary jaw, so that the cut may be parallel with the opposite side. When work that is in the rough is held in the vise it is advisable to place between the jaws and the work a slip of heavy paper or thin paste board which will increase the holding power of the jaws and remove the danger of the work shifting under the cut. After the work has been placed between the jaws and held by a slight pressure, it should then be rapped down onto the bottom surface of the jaw by a heavy mall or hammer by two or three sharp blows until it shows by the sound of the blow that it is well seated, then the jaws may be securely clamped.

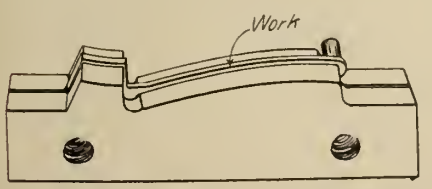

Fig. 5.—False Jaws for Sewing Machine Part.

To Hold Thin Strips.

When it is desired to hold thin strips of work between the jaws parallel of sufficient height must be used to bring the face of the work to be milled up above the top edges of the steel jaws. When taking finishing cuts on work of this character it is best to insert pieces of tissue paper under the four corners of the work to test the fact of its being seated upon the parallels or the bottom of the jaw. With the work held between the jaws firmly the hammer or mall is used to rap it down until all four pieces of tissue paper hold with the same "bit." By using this precaution it is possible to mill a piece of work to within narrow limits.

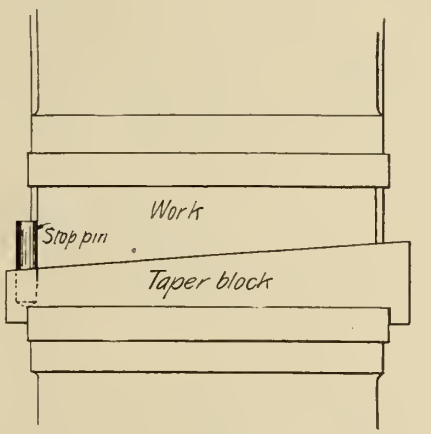

Fig. 3.—Vise Arranged for Holding Taper Work.

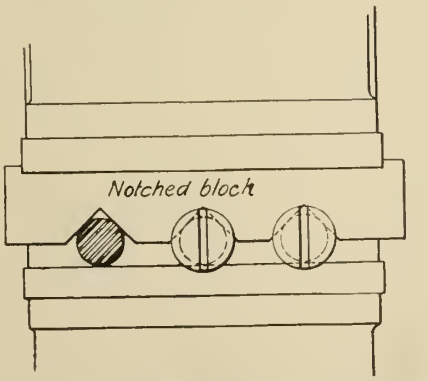

Fig. 4.—Vise Arranged for Holding Small Screws.

Method of Holding Round Work.

In the former article mention was made of the means made use of in holding work of other than the plain rectangular form.

Fig. 1 shows the vise arranged to grip round work, such as shafting, etc. In this case a loose "V" block is dropped in between the jaws and used to hold the work as shown. This method is only suitable for small work, as the block takes up considerable of the room that could otherwise be occupied by the work itself. However, for work that can be held in this manner it is a good method and one that is simple and inexpensive to make up. For a larger range of work the rig shown in Fig. 2 will be more satisfactory. This arrangement consists of special shaped jaws used in place of the plain steel jaws and held securely in place by the regular jaw screws. The angle of the beveled side is 10 degrees. The jaw is made with a straight portion at both top and bottom of the jaw and parallel as in the plain jaw. With jaws of this shape the work is held down against the bottom surface of the opening by the beveled faces. The work would have small chance of moving either lengthwise or by rotating about its axis.

With jaws of this shape two round pieces of work may be held with the same security as that of one piece. Work of small diameter may be rested or a

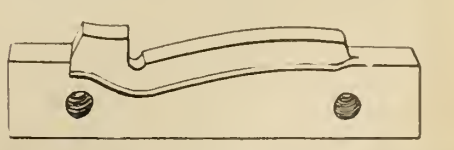

Fig. 6.—Back False Jaw for Sewing Machine Part.

parallel strip high enough to bring it in to the range of the beveled surface. A vise fitted with these special jaws is not limited to round work, but may be used with the same facility as one fitted with the regular jaw.

It is one of the faults of the vise to tend to force the work out of the jaws, especially when the steel facings are badly worn. Now, with the design of jaw shown in Fig. 2 the pressure is exerted at the upper portion of the jaw so that the tendency to force the work out should be greatly decreased. Jaws of this shape should find a large range of usefulness and should become more common.

Vise for Holding Taper Work.

A variety of work that gives lots of trouble to the user of the vise is taper work. Fig. 3 shows the logical way out of the trouble. This is merely in using a block, one side of which is planed to the required angle and the other fitted over the back jaw to hold it in place, as the tendency would be to shoot out at one side. The stop pin is put in the position shown to hold the work from shifting endwise. This arrangement makes a very easy way to avoid trouble with such work.

To Hold Screw in Vertical Position.

Can anyone think of a more bothersome bit of work than the holding of a screw in a vertical position between the jaws of a vise in the process of slotting the head? Fig. 4 shows an arrangement which does away with all trouble from the shifting of the screw to an angular position, and also facilitates placing it with regard to the position of the slotting saw. In the figure is shown a block with three notches of 90 degrees each on one side, and which is fitted over the back jaw on the other side, holding it in position laterally. By using such a device it is possible to hold a number of screws in a predetermined position in the path of the milling cutters used in slotting the head so that time is saved by it, not being necessary to set the slide each time, and also making it possible to slot the screws in gangs, which is also an advantage.

The use to which this arrangement may be put can be extended to cover any work of this character. Take, for instance, milling the heads of square headed screws. By using heading mills or side milling cutters in gangs, milling two opposite sides of the square at one pass of the cutters, then, loosening up the vise jaw, under the screws by lining up the milled side parallel with the vise jaw by means of a parallel strip or straight edge held against the flat side of the head, clamp the screws in this position and then make another pass of the cutters. The head milled in this manner might not stand very close inspection as to being absolutely square, but would answer all practical requirements. Further uses for this arrangement could very likely be found if one cared to go deeply into the matter.

Great Variety of Work Can Be Done.

A great variety of cuts may be made upon irregular work held in the vise if suitable fixtures are made for same. Nowhere is the vise used to such advantage as in the shops of the large sewing machine manufacturies, of small arms works and typewriter factories. The many small parts made from rough forgings and from the bar, in many cases, in these factories are, to a large extent, held in vises with specially arranged jaws. As mentioned in the former article, the jaw is made to conform to the shape of the edge of the work, being milled so that it is held securely against chattering. These jaws are also used to set the work in the proper position for the operation. In Fig. 5 is shown the jaws used to hold a sewing machine part during the milling operation. It will be seen that they follow the general outline of the edge to be milled, while not absolutely conforming to the shape of the piece they do support it along the edge operated upon. It would be rather unhandy, and a time-wasting operation to set the piece properly in the jaws unaided by some means or other.

The proper position that the work should take in the jaws is located by the pocket that is made in the back jaw. This pocket is so shaped that when the work is dropped into the pocket it will take the proper position with relation to the axis of the milling cutters. The pocket is clearly shown in Fig. 6, which represents the back jaw standing by itself.

The depth of the pocket is just sufficient to allow the sliding jaws to pinch the work when brought into contact with it. These false jaws are hardened so as to withstand rough usage and to prevent burrs from forming and also to prevent wear.

The vise can, with a little ingenuity, be converted into a very efficient fixture for holding irregular as well as plain work by working somewhat along the above lines different methods of holding the work suggesting themselves with each job that is tackled.

In describing the different styles and types of vises used in connection with the milling machine mention has not been made of some forms that are in the same category as the vises described, but are better classed as jigs since their use is, in many cases, limited to a singe piece.

---

*Firing With Soft Coal**

Bringing out the importance to manufacturers of having good firemen, and the necessity for firemen to study laws of combustion.

By Geo. D. Fowler.

It is too generally assumed that in firing steam boilers the fuel was burned under conditions over which the engineer or fireman had little or no control and that any man who could keep up steam was equally as good as any other man. This idea was erroneous. In a steam plant consisting of 300 h.p. a test showed that one fireman evaporated less than 8 pounds of water per pound of coal burned, while another fireman evaporated over 9 pounds, the difference between the two results being exactly 2 pounds of water per pound of coal in favor of the latter. A good deal of the waste generally attributed to the steam engine was in reality due to lack of knowledge and skill in the boiler room. It was now well known that a certain quantity of air was necessary to perfect combustion, and that too much air detracts from the economy, and injures the boiler. A glance at his fires, a knowledge of his chimney draft, a look at his dampers, and an understanding of the work his boilers were doing were quite sufficient to guide the skilled and experienced engineer without the use of the thermometer. He will have the fire kept at from 6 to 9 inches thick, a little thicker at the back end of the grate and along the furnace walls and in the corners, because the heat radiated from the side walls and the bridge causes the coal in these places to burn faster than that on the rest of the grate. The fire is kept solid and in good form by quickly sprinkling a thin, uniform layer of coal on alternate sides of the furnace at frequent intervals and by filling in such parts at may burn hollow, and through which the cool air in the ash pit will pour up freely and will chill the gases of combustion, thus lessening the efficiency of the boiler. The careful man will guard against such conditions occurring. He will have the grate surface properly covered with an incandescent bed of fuel, except near the doors, where a row about 15 to 18 inches wide, and built of fresh coal, extends across the front

* Presented before convention of Canadian Association of Stationary Engineers, Guelph, August 13, 14 and 15.

end of the furnace. The heat to which this row of fresh coal is exposed, causes it to coke, and to give off the inflammable gases that it contains, which are burned as they pass back over the incandescent bed of fuel. When brisk fuel is needed, this mass of coke is broken up and distributed over the grate. When the fire has again become incandescent, fresh coal is put to coke, and so the firing continues. The paper discouraged the practice of firing heavily only at considerable intervals, as it did that of heaping the coal up in the centre of the grate, leaving sides and corners practically bare. After putting on a fresh fire, it is a good plan to leave the furnace door open—about a half or three-quarters of an inch—until the fire has burned up a little, so as to admit an extra supply of air—that which passes up through the grate being checked for a few moments by the fresh fuel. The air thus admitted will greatly assist in consuming the gases that are given off by the fresh coal. If the door is kept wide open, the boiler will be cooled down and may be severely strained. As soon as the gases are burned off, the door should be kept tightly shut. A majority of the machines to consume or prevent smoke have turned out not to be very durable. Smoke may be prevented if only perfect combustion can be attained, and most of the smoke may be abated with careful hand-firing. If firemen would give close attention to the laws of combustion and put their knowledge to practice they could more than double the value of their services and their employers would no doubt be quite glad to pay for these.

The Art of Handling Men

Facts, Fancies and Opinions concerning the Handling of Men in Industrial Life—Gathered from various sources, including the writings of James H. Collins in Saturday Evening Post, and some happenings in Canadian Shops.

As to the relative importance of system and the personal or human element in dealing with employees in industrial life, there is as much diversity of opinion as there is diversity of human nature. System is a great thing, but so is personal magnetism. System without personality is pretty dead and is not a breeder of enthusiasm ; but personal treatment without system will surely lead to confusion.

When it comes to the human element in handling employees there is a wide difference in methods.

Mrs. Ella Rawles Reader, the "woman financier," once conducted a typewriting office in New York, with sixty girls. To insure sympathy she made it a rule to kiss them all the first thing every morning.

Captain Bill Jones, who was America's greatest steel maker in his day, sometimes started the morning's work by discharging a lot of his bullies and hiring them all over again in the afternoon.

That's carrying the human element pretty far. But look at some of the indoor organizations, and it often appears as though routine ran them. When men are able to make reports, take their cue from an authority chart and put a grievance into a typewritten statement, things often run so smoothly that personality seems a secondary factor. But it seldom is. Time and again have experts worked out a mathematically accurate system for running a great organization, and set it going under their own supervision on a mathematical basis. It runs until they leave and then runs down. Everything was there but personality.

When the Human Element Counted.

In a Canadian machine shop a superintendent was discharged because he did not mix with his men. He hadn't the gift of being one of them and superintendent at the same time. He was superintendent only. He did not bring the human element into play. System did not make up for it. He did not make his men produce as much as some other men could.

Another case of where the art of handling men counted is that of a superintendent of a railway shop in Canada. Some wondered why he held the place. His knowledge of the work which he controlled was not striking, nor was his executive ability of a type to arouse comment. But when you saw him employing labor, or noted the attitude of his mechanics towards him, the problem solved itself. He knew the art of handling men. He brought personality to play and it proved a winning card.

This human element counts for an awful lot. Look among the contractors, the builders of bridges, tunnels, dams and skyscrapers, and it will be found that every man on one of their jobs is playing a game. These employers fascinate the mind. They can organize a working force among Bedouins of the desert and reconcile warring Hindu castes. They can take the thick-skulled African native, who for centuries has had no conception of time, and could not comprehend the purpose of a watch, and interest him in breaking a world record in digging, or in beating some other contractor half-way round the globe. These men make work a game. They can set 10,000 laborers straining to finish a contract a few days ahead of a rival who is often only a figment of the imagination. The job starts off with a "Hurrah!" component that seems to be the best possible cohesive for an organization of elemental men. Frequently an application of fists is necessary, or a display of revolvers. The work is usually the most dirty and disagreeable in the world and to a high degree dangerous, and seldom any too-well paid. It calls for the sudden organization of great working forces in places where men are scarce or have never learned how to work. Yet the contractor carries on his enterprises with a vim, speed and certainty that make other industrial problems appear mighty small in comparison.

Theodore Starrett is one of the pioneer skyscraper builders in this country, and credited with a vast amount of steel construction. It is a saying among steel workers that "every floor of a modern skyscraper costs a human life." Records of accidental mortality among steel workers partly bear this out. Starrett has been building skyscrapers for more than twenty years, and has had constantly under him a force varying from one thousand to fifteen thousand men. In all that period his mortality bill will not amount to a dozen lives lost, and for more than ten years he had the record of not a single fatality on one of his jobs.

Men lose their lives in steel construction chiefly through the pressure that is put on them for speed. Every steel construction job is a race. Starrett has been as speedy as the rest in putting up skyscrapers. He holds some world records. But he has been able to make work a game and a race, and still safeguard his men by good management. Steel workers do not always take kindly to safegnards. They are daredevils at heart, and will steal a ride on a girder while the boss' back is turned, straight up 200 feet in the air on a single strand of steel rope. "Beat him to it" is a maxim of this trade, and nothing is an obstacle in a race. A railroad car was derailed and thrown where a wall was to go on one of

Starrett's jobs. "Brick it in," said the foreman, and but for the arrival of a railroad wrecking crew the car would have become part of the building. A trainload of brick was sidetracked fifteen miles away and the men halted for lack of material. The railroad company put forward its stereotyped plea of being unable to handle traffic. "Go to it," said the foreman. A yard engine was taken away from its crew and that train hauled up on to the job in two hours.

The eight-hour-day is being asked for by machinists in Canada just now. Manufacturers oppose it because of the decreased output it would mean in their shops. One superintendent thought an eight-hour-day was of sufficient length, and thought that he could get as much work done in the eight as he did in the ten. Now his men are working eight hours, and the output of the shop has not suffered. The shop is run on the same system, so system is not the cause. Again, the human element—the act of handling men—comes into play. There is very seldom any labor trouble in that shop, because the men are dealt with in a way which appeals.

The Human Element in Large Organizations.

But what about this human element when the organization is too large for personal supervision! Return to Starrett and his steel buildings.

Formerly Starrett worked by the old system, one building at a time, and the job under his own eye. But now he has thirty to forty jobs going simultaneously. Yet his casualties are almost negligible.

Ask him how he does it, and, although he is a Bachelor of Arts, he will tap the nearest wood and say that it is bad luck to talk about good luck. Bad luck means the death of twenty men on a fifteen-storey building. What Starrett really has done is extend his system of individual supervision. When he hired and bossed the men himself it was a matter of judgment to pick the most agile and intelligent—it would probably not do to say the most careful in this business, though that might count, too, in a man's care for others, if not for himself. He picked good foremen—not the sort of man who cursed a steel worker from the sixth storey and then threw a bolt-key at him as is said actually to have happened in the construction of a building where nineteen men lost their lives. To-day Starrett is out of immediate touch with men. But he supervises the selection of foremen, supervises promotion, and keeps up the morale of his organization. When this is maintained, the force can be driven as fast as any other and with safety.

Work as a Game.

At the Edgar Thompson Works, belonging to Carnegie, in Braddock, Pennsylvania, an enormous broom was formerly to be seen over one of the furnaces. This broom shifted from stack to stack, and wherever placed indicated that the furnace beneath held the world's record in steel production. By and by other steel plants as far away as Chicago became interested in this little game of solitaire, and set out to break records, too. When a new one was established the figures were telegraphed, and the victorious furnace hoisted a broom. In a few years the game became more important than the candle, and brooms were abolished because they could not be shifted fast enough.

This idea was introduced into the steel industry by Captain Bill Jones, a famous character in the steel country around Pittsburg. Jones was born in Pennsylvania, of Welsh parents, and rose from private to captain in the Civil War. Beginning in Andrew Carnegie's employ at two dollars a day, he was eventually made superintendent of the Braddock plant. In less than four months he had doubled its output with the same equipment. A year later he was making steel six times as fast, and later still he doubled that record. His control of men was wonderful. He mixed profanity with quotations from Shakespeare, and would discharge his best workers right and left when in a temper. But the crack steel makers of all that district flocked to Jones.

He had three formulae for men: 1. They must be young and ambitious and able to make steel in strong but pleasant rivalry. 2. They must have an eight-hour day to keep them fit. 3. To make steel fast and well, he believed, a mixed nationality of workers was essential. Captain Jones lost his life among his men, dying of injuries received in a furnace accident and a Hungarian laborer was killed alongside him.

Consulting Employees.

Sometimes a manufacturer finds it a good scheme to find out the opinion of employees upon how things should be run. He finds that if the employee knows that his opinion has some weight with the boss, things run smoothly.

A large industrial plant had friction until the committee plan was adopted—each department head by a committee of not more than six, which could take up difficulties of its own work, and also be called into general advisory councils. There was little trouble after that, for the men who knew things had a voice, and all work went on under arrangements previously discussed, understood and agreed to, and workers in different departments got acquainted with one another—perhaps the most essential point of all. The idea of "get together" is a regular Hague tribunal of peace in industrial affairs. One organization has carried it so far that a conference must not only be held in all difficulties, but those who come to the conference are never permitted to leave in pique, anger or dissatisfaction. Such discussions seldom run along like the afternoon meeting of a sewing circle. Energy comes to confer—high-priced energy—and sometimes politics and personal rancor, but the difficulty is threshed out in the open and no matter how the decision finally falls, this rule brings everything to a close in sweetness and light, largely because it is a rule for just such occasions.

Where a System of Military Principles is Effective.

A certain contractor has adopted military principles in handling men, laying down definite lines of authority in a little handbook carried by all his superintendents and foremen. This book, or "field system," corresponds to the army manual in many ways.

With scattered parties working on contracts in different States, hiring labor under local conditions, it was found necessary to establish some standard system of procedure to insure uniform efficiency and cost. As a beginning, each superintendent was asked to write out rules for his own kind of work—not ideal ones, but rules covering methods actually in use. The first lot was crude, but it formed the basis upon which to build better. Prizes were offered for good working rules and suggestions, and, for months, the system worked lamely because there were many changes. Eventually fewer and fewer prizes were paid, because the system had reached basic principles. To-day it makes work on contracts independent of local conditions.

All employes are required to follow the field system rule for performing specified work until something better is adopted, but each has the right to suggest other methods and can get a personal hearing. Superintendends and foremen go from the home office to a contract a thousand miles away, and employ local labor. But they disregard local customs. There are, for instance, many different ways of mixing mortar. But this field system specifies that all mortar shall be at least two weeks old before it is used. When local custom says, "But this is the way we always do it," the field system backs up the foreman. It may be necessary to explain that the boss is a crank, and introduce the little red book as a compilation of his whims, but, in the end, the work goes on according to tactics. "He pays the

wages, you know," is a knockdown argument.

This system contains complete lists of tools to be taken to each kind of job. It cites twenty-five different kinds of work to be performed on rainy days, when the main job is suspended. It gives forms for making out requisitions, reports, tool-lists, pay-rolls, receipts, etc. It deals minutely with steps to be taken for the care of machinery, materials and equipment.

This contractor's forces have used large quantities of dynamite. Plain rules cover the storing and handling of high explosives. Notwithstanding numerous accidents that are constantly occuring all over the country through the use of dynamite, manufacturers of explosives maintain that judicious handling will make it as safe as sawdust. And the experience of the men who work under this field system bears them out. No fatality has ever occurred on one of this contractor's blasting jobs, and only one accidental explosion, in which some excellent sprinting was done, but nobody hurt.

The book gives rules for selecting men, and is reinforced with a card system by which an office record of every competent man is kept, with data as to class of work he is best adapted to. System in selecting men has made possible a record of only four fatalities in ten years. Men seldom kill themselves, says this contractor, but their carelessness leads to the death of others. Only one man ever killed himself, so far as the records go, and he, very curiously, furnished an indorsement for the field system.

Under "Derricks" appears a rule specifying that all derrick-irons shall be procured through the home office. This employee disregarded that rule and purchased equipment from a local concern. Several days after, a derrick-iron broke, dropping a boom upon him, crushing his skull. Investigation showed a hidden blowhole in the iron. Derrick-irons sent from headquarters are made trebly thick to guard against just this danger.

The book gives formulae for mixing every variety of mortar, cement, etc.; for measuring materials and work; calculating weights; tables showing amount of work to be expected from different types of machinery. When a rule cannot be put into two or three lines of text, then diagrams and photographs are used to make the idea clear. Another notable feature is the index, which is so exhaustive that each six pages of text has a page of index, and any subject may be found instantly.

The important element to be incorporated in such a manual of authority is good sense—practically. Bureaucracy will not do—"the heavy curtain drawn between the right thing to be done and the right man to do it," as Balzac said.

The Social Feature Counts Too.

In highly efficient organizations will usually be found a vigorous social life that counts for a good deal. They not only have baseball teams, but the teams that win. They celebrate birthdays, anniversaries of long service, completion of important contracts. They begin things by laying a corner-stone and wind them up with the presentation of a loving-cup. The employer who fancies that these social functions are wanton frivolity, is commonly the man whose business pays twenty per cent. dividends to stockholders at one end and is harried by strikes on the other.

Five hundred drillers and "sand-hogs" sat down to a dinner at Sherry's a few months ago to celebrate, with engineers and capitalists, the completion of a tunnel under the North River, New York. And another striking bit of practicality growing out of such social life was the recent capture of a bond clerk who disappeared from a metropolitan trust company one Saturday morning with a large sum in securities. The police did not know him, so the president scattered his office force to depots and ferries. The culprit was captured through his wife, whom all the employees knew by reason of their association with him on an office bowling team, and the securities were recovered.

Training and Industrial Schools a Factor

Training of apprentices is a very live industrial question to-day. The Pennsylvania Railroad has invested three hundred and fifty thousand dollars in such a training school to attract boys from the high schools. The Steel Trust has another. A certain western manufacturing concern has not only an apprentice school, but other training departments that educate machinists and assemblers before they are sent to regular departments.

A large automobile factory now being built in the United States will have its own training school in a separate building, and boys entering it from the public schools will be taught trades in one-third the time needed in the factory, and with more thoroughness, while the work they turn out when at school will be paid for and used in the factory.

A manufacturing company in Canada has arranged to take boys from the high school for shop training. By this method it is hoped to sort the boy who has natural mechanical tendencies from the one who has not. The first will be encouraged, and in this way a good class of mechanics will be obtained.

Germany's industrial system is to-day regarded by many observers as the ideal one in its organization, its manual training features, its efficiency. It is continually being held up for the emulation of British and American employers. Whatever merits or demerits it may embody, Germany's system is military to the point of paternalism. She trains her worker, puts him into the factory, keeps him employed through state bureaus, insures his life, pensions him in old age or disability, boards and lodges him while out of work, letting him pay in either money or labor, assigns him to relief construction when dull times come, helps him secure a home in prosperity, treats him in sickness and loans him money on his belongings. In fact, the state goes almost to the point of coming round every night to tuck the German workman into his bed.

TORONTO EXHIBITION OPENED.

Once again the Canadian National Exhibition has been opened at Toronto, and its reputation of being better than ever each year is still maintained.

The appearance of the grounds has been greatly enhanced by the erection of the three new buildings, the horticultural building, the railways building, and the new grand stand.

The machinery exhibits, in which readers of Canadian Machinery will be chiefly interested, are more representative than they have been for some years. Last year there were only two exhibits of machine tools in the machinery hall, while two American manufacturers, the Gisholt Machine Co. and the Landis Tool Co., exhibited tools in the process building. This year there are four exhibits of machine tools in the machinery hall, the Gisholt Machine Co., the London Machine Tool Co., H. W. Petrie and the A. R. Williams Machinery Co. The London Machine Tool did not exhibit last year. Other new exhibitors in the machinery hall are: Bordon Canadian Co., Cook Motor Co., Evans Rotary Engine Co., Schumscher & Boyle, Hornby & Son, Crossley Bros.

In the way of producer gas plants, there are more firms represented this year than last, although one has dropped out and a good feature this year is that these exhibits are in the machinery hall instead of in the process building.

The rotary engine is in evidence this year, there being two engines exhibited, one of the Manson Manufacturing Co. and the other, the Evans Engine Co.

It is to be hoped that before another year comes round there will be a new machinery hall. That is the one big necessity at the exhibition now. Then instead of four exhibits of machine tools there will be a dozen, and instead of being three exhibits of wood-working machinery there will be six or eight.

CANADIAN MACHINERY
and Manufacturing News

A monthly newspaper devoted to machinery and manufacturing interests, mechanical and electrical trades, the foundry, technical progress, construction and improvement, and to all users of power developed from steam, gas, electricity, compressed air and water in Canada.

MACHINERY MARKET CONDITIONS.

At the beginning of the fall months, when business men are again getting down to the hard grind after the holiday season and the warm summer months (not so warm this year, though), seems a fitting time to review the machinery market conditions in Canada, and discover how business has been during the past year, and what prospects are for the coming year.

As everyone knows Canada has just entered upon a period of great agricultural and industrial expansion. The whole world looks to Canada as a country of almost unlimited resources. People from all parts are flocking into the country. The population is increasing at a tremendous rate. The great Northwest and the vast mineral areas provide means for prosperity. There simply must be immense development in Canada during many years to come, and thus there simply must be an ever-increasing demand for all kinds of machinery for many years to come.

Naturally, in a country which is developing rapidly, there will be need of all available capital, and there may be occasional times when money will be pretty tight; but the only thing which could materially delay this prosperity would be a decided crop failure. Although crop returns this season will not be as good per acre under cultivation as in some years in the past, yet the yield will be fairly good. There is a lot of talk about the tightness of money at the present time, and there are varied opinions as to the result it will have; yet in all probability things will come back to normal conditions before the situation is felt seriously. Foreign capital has great confidence in Canadian enterprises, which is well for a country needing so much money for development purposes as Canada does.

During the past year, machinery manufacturers and machinery dealers have found business exceptionally good, so much so, that there are very few manufacturers in Canada who have not found it necessary to add to their plants in some way. Many plants have been working overtime, and all are busy..

Following are some expressions of opinion as regards the machinery market conditions by some Canadian manufacturers and American manufacturers who are directly interested in the Canadian market:

The Colonial Engineering Co., Montreal: "Business has been exceedingly good with us, considering that we opened up in Canada only on May 1st, since which time we have obtained a number of large contracts. The money market is certainly in a depressed condition. We think it is because there is more work to be done than there is actual funds to do it with. The general prosperity is exceedingly marked both in the United States and Canada. The ratio between the actual currency in circulation in the two countries and the stocks and bonds outstanding is too great. Over-capitalization in the United States is probably the direct cause of this condition."

A Montreal machinery supply firm: "With regard to deliveries we may say that generally speaking these at present are very slow both from the States and from England. With regard to monetary conditions we share the experience of most of the dealers in so far that we find it very difficult, indeed, to get in our collections."

The Packard Electric Co., St. Catharines: "We have been considerably handicapped in our work during the past year on account of slow deliveries of raw material of all kinds. Copper, which enters largely into the manufacture of our products, has been and is still very uncertain, delivery depending on the sizes and quantity

ordered. We are obliged to place our orders some time in advance, and for larger quantities than would be necessary if more prompt deliveries could be depended upon. In consequence, this means the tying up of more capital than is the case when deliveries are prompt.

"Business for the past year has been exceptionally good, but some of the large propositions contemplated may be delayed or postponed on account of the stringency of the money market."

An American machine tool manufacturer: "The export business—especially European demand—has been larger than ever, while Canada is unquestionably a promising future market for American machine tools.

"With reference to the long deliveries, this, of course, has been a considerable handicap, but the buyers now realize that this is a necessary condition of the market, and are making their plans far enough ahead to accommodate themselves as to deliveries.

"The speculative feature of the money market makes all business more or less on the surface, but if the underlying bases of prosperity are there, beginning with good crops—manufacturers need not be especially concerned with regard to the manipulations on Wall Street."

Cleveland Automatic Machine Co.: "We wish to say that we have been handicapped very much on account of actually receiving more business than we were able to handle.

"We do not expect any increased business, because, as far as we can grasp the situation, times are not as good as they were six months, or a year ago. We do not see any possible chance of a great slump in business, but, nevertheless, it has settled down to a great extent.

"We are sorry to say that our business in Canada has been exceptionally poor. The reason for this we cannot explain. We have sold more or less tools in your territory during the last fifteen years, but even though business is so good the world over, Canadian manufacturers seem exceedingly slow in purchasing our automatic machines. Whether it is on account of the tariff, or some other cause, we are unable to determine. We have, from time to time, in years gone by, tried to sell our machines through agencies who handle American machinery in your country; we have also had a representative handling our tools independent of agencies, and, latterly, we are using advertising space to assist us in our business, and you would be surprised at the small number of inquiries we receive."

The American Tool Works Co., Cincinnati: "We are running our factory to its full capacity, with plenty of orders ahead at present. There is no doubt a lull in business generally throughout the United States owing to the financial situation and unless there is an improved condition of same ere long, it will have its influence on general business. We find our foreign business increasing, which will doubtless fill the gap that may be occasioned by a falling off in the States. Our Canadian business is large and promises well for the future."

There is a feature in the machine tool business in Canada at present which deserves attention. This is the efforts which are being made by Canadian machine tool builders to make their product as good as is obtainable. The complaint has been made in the past that the majority of Canadian-made tools did not come up to the standard set by American manufacturers. It was claimed by buyers that careful work was not put on them, and that they could not be depended upon for very fine and accurate machine work. Then the minor point of finish was also complained of.

This is now being all changed. The necessity of being up to date in every particular is being fully recognized, and considerable effort and money is being spent in this respect. As the market broadens this will be more and more noticeable, and after a while specialization will take place, providing opportunity for the best and most accurate work. Even now certain firms are making specialties of certain tools in anticipation of the future market condition.

AUGUST METAL MARKET.

Never before in the history of the metal trades has there been a depression so acute and of such long duration as that which has prevailed in the Canadian metal markets during the past two months. With the exception of pig iron, the business in all metal commodities is characterized by complete stagnation. The only thing which will induce consumers to buy metal is dire need of that commodity to keep their factories in operation. Now that this period of depression has become so prolonged, it has taken on a very serious aspect and a little more than the usual apprehension expressed by dealers is noticeable in metal circles.

The present stagnation is attributed to the usual annual idleness of the furnaces during the summer months and mostly to the stringent conditions existing in the money markets, due to speculation and a more than ordinary foreign investment.

Pig iron during the past month has experienced a steadily increasing demand. Opinion was expressed by a Montreal dealer recently that upwards of 10,000 tons of pig iron have been sold in local circles within the past fortnight. Canadian prices have been firm and subject to few or no fluctuations. The English market has been variable. One week prices are high; the next week they fall to a minimum. Absolutely no buying has been done in the American market, partly because of the prolonged idleness of the furnaces and partly because of the uncertainty prevalent in speculative circles.

Ingot tin continues very weak. The buying public have no confidence in the market. Prices fluctuate, and until a level of prices has been reached which is low and which will guarantee steadiness, consumers will remain coldly indifferent to buying. The price ruling throughout the past month for Lamb & Flag and Straits is $44. Minimum premiums for immediate delivery are offered, and little activity exists.

Copper is still very weak and little demand is experienced. Market conditions in Canadian circles are unsatisfactory, due to stringency of money and due to the demoralized conditions in the American market. Regarding this, the Iron Age (August 15) says: There is no exaggeration in the statement that the market is demoralized. The difference between the figures given to the public by selling agencies of the leading producers and the figures at which consumers can buy and are buying, though their wants are very meagre, is so great that it would be futile to name producers' alleged quotations. Transactions are of such limited proportions that a sale of 100 tons is nowadays considered a large quantity. Since our last report the London market for spot has dropped from £82 10s. to £76 10s., while futures fell from £80 15s. to £73 10s.

Although H. H. Rodgers' arrival in New York City did much to stimulate buying with the immediate decline in the prices, the stimulus he administered was only temporary and it will require an event of this importance to again enliven the market.

Antimony has continued weak throughout the month. Little business in it is being transacted. The price for Cookson's continues at 8c.

Machine Shop Time and Cost System

A simple and effective Time and Cost System as used in the shops of John Bertram & Sons, Limited Premium System of arranging work found satisfactory.

The time and costs systems used in the plant of John Bertram & Sons, Ltd., Dundas, Ont., are very simple and effective, and a description of these systems will probably prove interesting and instructive to readers of Canadian Machinery.

Time Recording System.

The time system is so arranged that each man keeps his own time. He registers his time of commencing and leaving off work each day on a time register, which is placed in a convenient position in the department in which he works. Then there is the Daily Time Card, on which he registers the time of commencing and leaving off each operation during the day. These daily time cards are made out for all the operations which are carried on in the shop, such as turning, boring, milling, planing, etc., and Fig. 1 shows one for turning. This turning card is used as an example throughout.

Upon commencing an operation the mechanic fills in the date, his name, his clock number, the order number, the number of his machine, and the number of the drawing from which he is working, all shown in Fig. 1. In the Bertram shops every order which is executed, be it very large or very small, has its number, and each piece contained in the machine or device constituting that order has its number. Also every operating machine in the shops has its number. Then he marks his card with a check mark under the hour at which he commenced, say 7 a.m. Upon completing this operation, say 11.15 a.m., he places a cross under eleven and also opposite the 15-minute mark, as shown. Thus it is seen that nothing less than a quarter-hour is recorded. This shows clearly that 4¼ hours were consumed on this operation, and this is recorded in the lower right-hand corner of the card under "hours on job," as shown in Fig. 1. The operator then proceeds with his next operation, filling out a second card as before (one card is used for each operation), but puts his check mark under 11 and opposite 15 minutes, as shown in Fig. 2, to show time of commencing, and then continues as before. If the job on which he is working is not completed on that day, he marks his card with the time occupied during that day, as shown in Fig. 2, and commences work the next morning with another card, as shown in Fig. 3 finishing at 10 a.m. This there is a record that 7¼ hours' work was put on drawing number 615 for 4007, 4¼ hours, on Aug. 2, and 3 hours on Aug. 3.

for each during the day. The total hours for the day is also filled in.

Similar cards to these are made out by all the mechanics in the shop, and in the morning all cards for the previous day are sent to the time department, where they are checked with each man's time register. Then they are sorted into their respective operations, and listed on a time summary sheet. On this sheet is recorded the hours of each operation on each order for the day, and there is a summary of the total hours of each operation for the day as well as the total machine hours. This is carried out with the aid of a Burrough's adding machine.

From this sheet the time is transferred to a time summary card, Fig. 4. On this card is summarized all the time spent in the different operations for each order. Looking at Fig. 4, it will be seen that the order number is filled in, and a description of order given; date of order is filled in and number of card, according to the length of time required to finish the order. From the time summary sheet each day the time spent on each operation is entered on this card, and is entered additively, so that as the columns marked Monday, Tuesday, etc., are filled in they will show the total number of hours put on that operation up to that time. For instance, supposing an order, No. 4008, were started on Monday, and on that day 2 hours of forging were done; this is entered as shown. Then on Tuesday 3 hours of forging are done. Instead of entering 3 under Tuesday, 5 is entered as being the total hours of forging up to Tuesday. This is carried out until Saturday. For the other operations the same thing is done, and at the end of the week there is a complete record of hours for the week on each operation, and the total hours on the order for the week is reckoned. A similar record is kept each week until the order is completed, when the assembled weekly cards give a complete record of time spent on the order, the last card showing total time.

Fig. 4.—Time Summary Card.

Description of Cost System.

The cost system naturally follows after the time system, and in this system a record of costs is kept on cards, there being a card for each order or article. Fig. 5 shows the front of this cost record card, and Fig. 6 shows the back of the same card. In Fig. 5 it will be noted that the order number and the number of the machine as sold are recorded. From the latest time summary card of this order number the total number of hours on the different operations can be filled in, and the cost computed according to the rate of wages. The total labor cost is carried forward to the back of the card, Fig. 6. For convenience of comparison the labor cost of the same machine executed in the shop at a different time and under different order numbers can be entered from previous cost record cards. In Fig. 6, the back of card, the amount and cost

of materials are recorded, data for which is obtained from the stock room. Thus the complete cost of the machine is arrived at. At the bottom of the card the selling price of the machine is computed by addition of percentage of profit which the company allows themselves. A record of the disposal of the machine is also kept, and the completeness of information regarding cost which is contained in the lower three sections of the card will be noticed.

Premium Labor System.

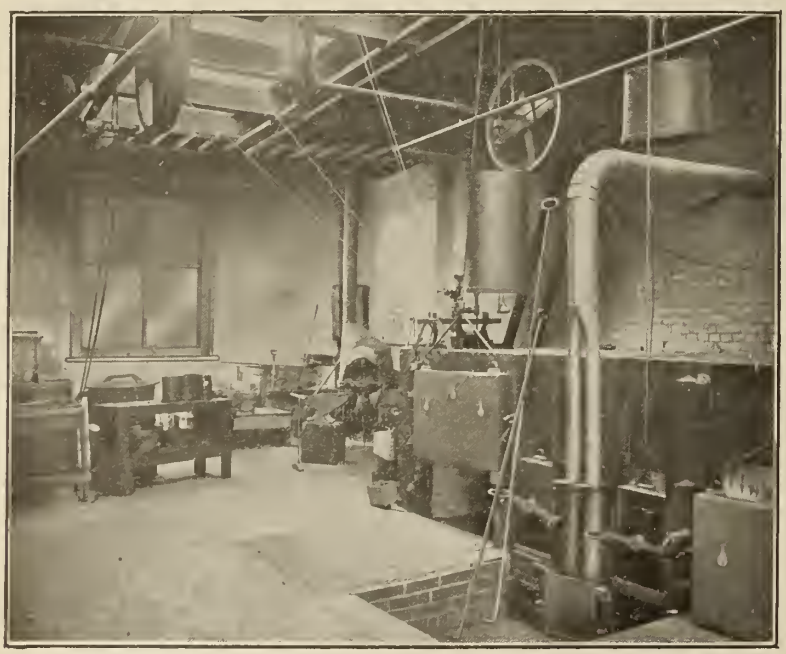
The premium system of paying for labor is adopted in these shops, and is giving good satisfaction. A time limit for each piece of work has been set, information for the setting of this limit being obtained when the shops were being operated by day labor. The time limit set appears to be very satisfactory to the machinists and other mechanics, and never mind how much less time than the time limit is consumed in doing certain pieces the time limit remains unchanged. The system is simply this: Five hours is allowed for a certain piece; a machinist does it in 3 hours, that is in 2 hours less than the time allowed. The machinist is allowed the 5 hours plus one-half the time which he saved, i.e., one-half of 2 hours; and thus he is credited with 6 hours' work, having worked for three hours. In case the time taken to do the work exceeded 5 hours, he would be allowed only for the 5 hours. Should a man attempt to work too quickly and do careless work, the time required to remedy his careless work is deducted from his time to the amount of the bonus time, but no farther. This man and the man who exceeds the time limit are watched, however, and necessary steps taken to make them improve if such is done persistently.

The manner of recording this is shown in Fig. 7, which is a time card given to the machinist with the foregoing explanation of the system, the manner of recording on this card can easily be understood by following the headings.

The Manufacture of Double Ball Bearings

Description of the manufacture of the Chapman Double Ball Bearings as carried on in the new factory in Toronto.

An interesting line of manufacture is being carried on by the Chapman Double Ball Bearing Co. in their new plant in Sorauren Ave., Toronto. The factory is built with every provision for extension, for which there is also plenty of ground space. Of the equipment an adequate idea can be obtained from the accompanying illustration, showing the different departments. In speaking of the manufacture of the parts, this equipment will be further referred to.



View of Furnace Room.

The balls and their caging are the chief parts of the bearing, and one of the first things is to have these balls absolutely true. These balls are brought from the United States, and every ball, before it is received, is micrometered. The cagings come from the presses, and the balls are assembled into the cages

The outside housing of the bearing is an iron casting. These castings come direct from the foundry, and in a few minutes on the lathe a groove is cut inside to fit the ring, and one on the outside to receive the dust cap.

The steel ring that fits into the housing is one of the most interesting items in a double ball bearing. This is the outside track on which the balls must race. These rings are the product of a special steel composition, and all steel used for this purpose goes through a special analysis. These rings are first reamed and trued on the lathe. This is done fourteen at a time by placing on an arbor.

From the lathe the rings are taken to the furnace room, where they are hardened and tempered. This furnace room is a very interesting department, and is very well equipped. The furnaces are gas-fired and the temperature is kept constantly by means of a pyrometer. The rings are placed in the furnace by the attendant, and when they become the same temperature as the furnace, which is according to the judgment of the operator, they are removed. Each ring as it is removed is doused in a vat of salt water, where it is left about 15 seconds. The rings are then placed on top of the furnace to dry after which they are put into a bath of special tempering oil. After a thorough soaking they are removed and thoroughly scoured with benzine.

After this each ring is tested separately by the tone test. The ring is struck, and according to the tone the attendant can tell whether there are any flaws. After this test the rings are taken to the grinding machine, where the minute uneven surfaces are removed. From there the rings go to the assembling department, and are fitted into the groove in the outer casing.

The conscientious care which is taken with the ring is duplicated with the cone, which fits over the sleeve and forms the inside contact surface for the balls. The cone is machined, hardened, tempered and ground in the same way as the ring was.

The check nut, which screws in under

the cone and keeps it in place on the sleeve, is also an important part, and after it is screwed into position, it is held on by a ring of set screws.

After being assembled, the bearings are all tested. The testing is done on a hydraulic machine, by which any desired pressure may be exerted upon the bearings, and the bearings are mounted upon a shaft which can be rotated at any desired speed. Thus a complete and thorough test can be given the bearing.

We have followed the different operations in a general way from the foundry or stock room right to the tested bearings, and this can be followed with greater interest if we glance at the accompanying illustrations.

Everything turned out by the company is built to standard, and the systems used throughout the shop are very simple and comprehensive.

A View of the Machine Shop.

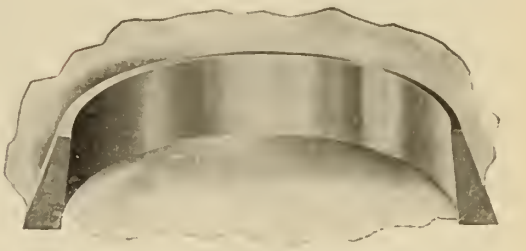
SOUVENIR WATCH FOB.

The souvenir watch fob which the E. H. Mumford Co., Philadelphia, Pa., are sending out is very neat. This could probably be obtained from the company upon application by mentioning this paper.

STANDARD PROPORTIONS OF MACHINE SCREWS.

At the Indianapolis meeting of the American Society of Mechanical Engineers, a new report was submitted on the standard proportions of machine screws, which embodies several changes over the report last handed in. Only three sizes remain the same as before, and additional sizes have been added to the list.

The included angle remains 60 degrees as before, and the flat at top and bottom of thread is still one-eighth of the pitch for the basic or standard diameter. There is a uniform increment of 0.013 inch, between all sizes from 0.06 to 0.19 and of 0.026 inch in the remaining sizes. This change has been made in the interest of simplicity and because the resulting pitch diameters are more nearly in accord with the pitch-diameters of screws in present use.



A Section of Bearing Ring Used in Ball Bearing.

The pitches are a function of the diameter as expressed by the formula

$$\text{Threads per inch} = \frac{6.5}{D + 0.02},$$

Showing Method of Assembling Bearings.

SCOTTISH NATIONAL EXHIBITION.

The arrangements for the Scottish National Exhibition to be held in Edinburgh next year have made good progress. The plans, subject to any alteration which may be deemed advisable, have been accepted, and work on the grounds and buildings will commence either at the end of this or the beginning of next month.

In the accepted designs the industrial hall, of 100,000 square feet and the machinery hall, of 20,000 square feet, are included in one magnificent building, and everything, both in connection with the structures and the grounds, has been planned with a view to charm the eye and at the same time to facilitate the commercial requirements.

NEW STEEL FOR TAPS.

Jonas & Colver, Limited., Sheffield, Eng., have lately introduced a new kind of tool steel upon the market, known as "Intra" steel. This steel is specially recommended by the makers for taps, dies, punches, chisels, etc. It is handled in Canada by Wm. Abbot, Montreal.

with the results given approximately so as to avoid the use of fractional threads.

The diagram, which is much less complicated than the one first used shows the various sizes for both 16 and 72 threads per inch, and shows, among other things, the allowable difference in the flat surface, between the maximum tap and the minimum screw, this variation being from one-eighth to one-sixteenth.

The minimum tap conforms to the basic standard in all respects except diameter. The difference between the minimum tap and the maximum screw provides an allowance for error in pitch and for wear of tap in service.

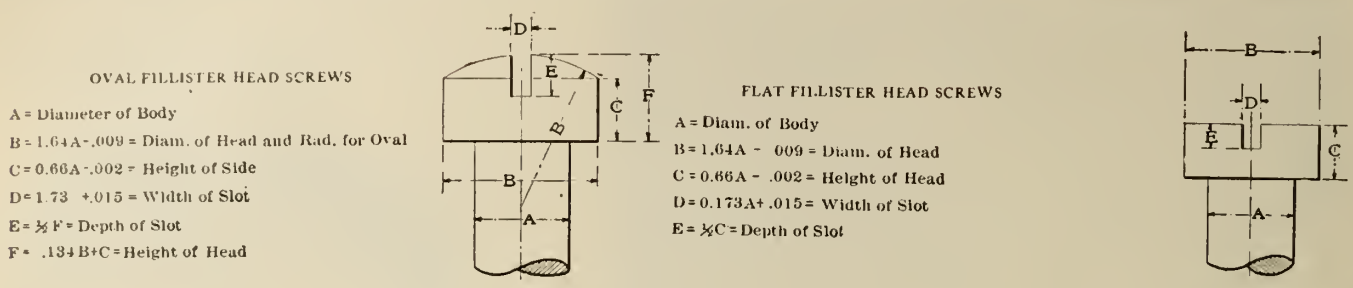
The form of tap thread shown is recommended as being stronger and more servicable than the so-called V-thread, but as some believe a strict adherence to the form shown might add to the cost of small taps, they have decided that taps having the correct angle and pitch diameter are permissible even with the V-thread. This will allow a large proportion of the taps now in stock to be utilized.

Tables of standard proportions have been prepared by the committee, and readers of Canadian Machinery may secure copies of these tables from the American Society of Mechanical Engineers, New York; or more compact tables have been prepared by the Corbin Screw Corporation, and probably copies of these could be secured through the society.

Proportions of Heads.

The accompanying illustrations show the four standard heads, and proportions of parts. Tables of proportions of these heads may be obtained in the same way as tables of proportions of screws.

A commission of German electrical experts and railroad officials, which was appointed to visit United States and Canada, to study interurban transportation facilities in these countries, are now on their way.



OVAL FILLISTER HEAD SCREWS
A = Diameter of Body

Improvements on Compressive Riveters*

A riveting machine designed by the author in which he gets the desired toggle joint movement, and at the same time secures automatic adjustment, in which the difficulties with the hydro-pneumatic machine have been eliminated Improvement in pneumatic hammers.

By CHESTER B. ALBREE.

In compressive riveter work there are two or three types which are quite familiar, the oldest type being the straight hydraulic machine invented by Tweddel in England, and later on, the pneumatic riveter by Allen of New York, who was perhaps the first to make it a success. Later came the hydro-pneumatic riveters. With the hydro-pneumatic riveter we have been making some experiments, and it was found to be advisable for several reasons, notably for greater economy of air, simplicity of construction and better action, to try to improve the methods that had been in use. In driving rivets the pressure required differs from punching materials in that in punching, the greatest pressure comes at the beginning of the stroke, when the punch comes down on the material. In riveting, however, especially hot riveting, the easiest work is when the die first strikes the rivet and the greatest pressure is required to finally form the head. That being the case, it can readily be perceived that a constantly increasing pressure would be the theoretically correct pressure to drive rivets. This pressure is most easily obtained by means of the toggle joint, which theoretically gives an infinite pressure with an infinitesimal movement at the end of the stroke. In practice, of course, we do not get an infinite pressure; but, as most riveters are of horse shoe or yoke type, the limit pressure is the yielding point or the bending point in the yoke. In straight toggle joint machines the general idea is shown in Fig. 1.

In practice we find that when the cylinder has made seven-eighths of its stroke the pressure line of the rivet dies rises up to about 15 times the pressure in the cylinder. By that time we would have traveled within about 1-16 inch of the final stroke of the machine, and beyond that point the probabilities are that there would be spring in the yoke. If we made the yoke strong enough not to spring at all, it would be so heavy as to be utterly unmanageable. So it is only necessary that deflection should not occur at a pressure below that necessary to drive the rivet. Hence in the toggle joint arrangement we have the best possible arrangement for driving rivets.

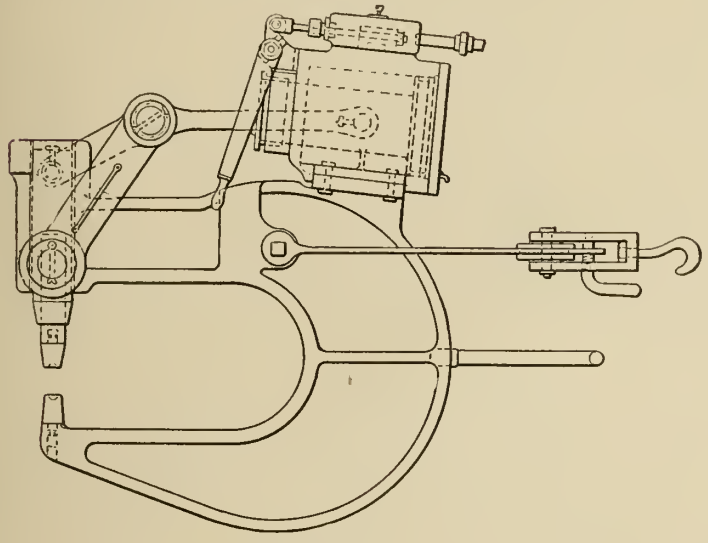

FIG. 1. GENERAL ARRANGEMENT OF RIVETER

But there are certain drawbacks in the practical application of the toggle pressure. The principal one is that its stroke is absolutely fixed. It never varies for a given leverage. In riveting you are liable to have 1 inch or 2 inches, or maybe only ½ inch thickness of plate, and in order to have the maximum pressure just as the die comes to the surface of the plate it is necessary to adjust the distance between the die and the point of maximum pressure by means of a screw actuated by hand. In work that does not vary it makes little difference, but in ordinary structural work, and boiler work, you have constantly to drive rivets through different thicknesses of material, and each time it will be necessary for the operator to adjust the screw. That requires a certain amount of skill, and if it is not done correctly the chances are that you will not drive the rivet sufficiently tight, if you do not close it with maximum pressure.

To overcome this difficulty of adjustment the hydro-pneumatic machine was devised, which is nothing more nor less than a hydraulic intensifier. The ram alone gives a very small but powerful motion, and it is necessary in riveting to have clearances, in order to go over angles, stiffeners, etc., so it is desirable to have a longer stroke. Of course we do not need high pressure over a longer distance than, say, 1¾ inches. The question, then, was how to get a clearance movement. This was accomplished by putting a little extra cylinder below the air cylinder. The air pressure acting on its piston forces liquid into the ram cylinder at low pressure, and by this means we get three or four inches of preliminary adjustment.

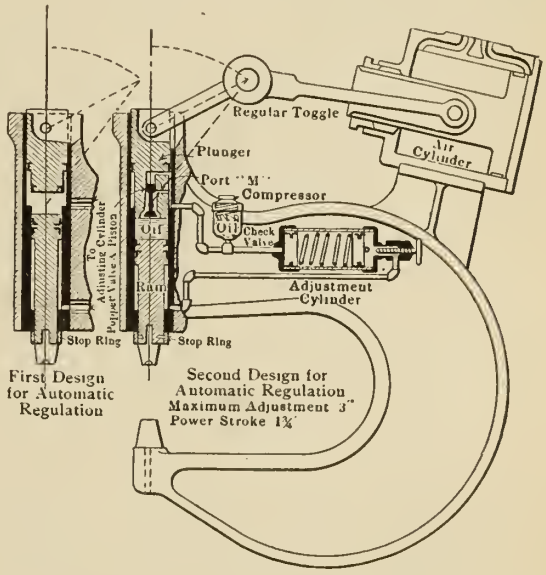

FIG 2. FIRST ATTEMPT AND PERFECTED DESIGN

The objections to this form are: in the first place, it is difficult to pack; and second, that in order to get two inches of die motion with a maximum pressure of 50 tons, it requires a 15 to 20 inch stroke in the air cylinder, and a very high pressure throughout this stroke in the ram cylinder and plunger cylinder; sufficient for the final closing pressure, thus wasting power. The practical advantage is that it does not require

*A paper presented before the Engineers' Society of Western Pennsylvania, by Chester B. Albree, president Chester B. Albree Iron Works, Pittsburg, Pa.

skilled workmen to adjust the dies; they adjust themselves. It occurred to us that we might get the desired toggle joint effect and yet have an automatic adjustment, and what I desire to bring out is the device for the accomplishment of this, which may be of interest to you.

In Fig. 2 is shown our first attempt and also our perfected form. As far as the toggle joint action goes, it is practically the same as the first machine described. The pressure from the toggle, in the first form of machine, is transmitted from the large area of the plunger to the top of the ram and also through a pipe to the adjusting cylinder. The ram being smaller in area and free to move, advances more rapidly than the plunger and continues until the rivet die on its extension strikes the projecting rivet. As the plunger continues, the pressure in the cylinder is limited by the pressure due to the spring in the adjusting cylinder, which is only 20 pounds per square inch, insufficient to upset the rivet beneath the ram. Hence the liquid will now displace the piston in the adjusting cylinder, the ram remaining stationary. As soon, however, as the projection on the plunger enters the ram cylinder the full toggle pressure is transmitted through the incompressible liquid to the ram, forcing down the rivet, and the differential area above forces the remaining liquid in the large plunger bore into the adjusting cylinder.

During the downward motion of the ram the liquid beneath it is forced into the opposite end of the adjusting cylinder, against the spring pressure. It is obvious that the ram may move its whole adjusting stroke; or not at all, up to the time that the projection on the plunger enters the smaller area; after which the further travel of the ram is that of the plunger, until the ram meets opposition greater than the pressure of the toggle, when it will stop. This arrangement, therefore, automatically adjusts the point of maximum pressure to suit the work. On the return stroke we have the direct pressure beneath the ram, as well as the suction of the plunger, to raise the ram to its original position.

Theoretically, this design was correct, and it worked very well indeed for about two strokes. At the end of the second or third stroke our packing was gone and we have found it impossible to hold the pressures. The trouble lay in the fact that we put cup leathers at the end of the plunger, and when the cup leathers entered the chamber, the moment the pressure rose to a high point it tended to cut the leather right out. So in order to make the device practically, as well as theoretically, successful, it was necessary to devise some scheme to have the leather cups, which hold better than any other hydraulic packing, move always surrounded by the walls of the cylinders, and pass no ports whatever. To do this and yet allow the liquid to pass freely from the upper to the lower part was rather a difficult proposition. We accomplished it in this manner.

Referring to the latter form, in Fig. 2, it will be noted that the extension of the plunger, when fully up, projects into the smaller area of the ram cylinder; and the cup leathers are used to pack it. In the interior of this extension is a valve of the poppet type, but having a stem carrying on its end a small piston.

This valve is normally held open by a spring. So long as the pressure above and below this small piston is the same, the spring holds the valve open, but when the pressure below is greater than above, the piston will move up, closing the poppet valve. This occurs only when the port M leading into the space below the small piston is closed, due to its passing from the large diameter bore to the smaller ram bore. When closed, the toggle pressure acts on the liquid below the plunger extension, raising the pressure sufficiently to move the small piston and connected valve, and later exerting very high pressure on the poppet valve, shutting it very tight. The adjusting action is precisely the same as in the first type, except that the liquid flows through the plunger extension instead of around it, during the adjustment part of the stroke. With this arrangement it will be noticed that all of the plunger and ram packings are continually enclosed by cylinder walls and pass no ports or openings, so that the packing leathers are not injured. I would say that the adjusting device is patented and the poppet valve device is now being patented.

In any device of this kind there is always a certain loss of liquid, due to a film in the ram (although, theoretically, the quantity of liquid is constant), and in the course of a little while there would be a partial vacuum inside and pressure on a cavity would not give good hydraulic pressure on the rivet.

It was, therefore, necessary to provide a constant source of supply of the liquid, so arranged that when the pressure rose in the confined liquid it would not blow out, but when there was a vacuum in the system additional liquid would run in.

This loss of liquid is made up from a small storage or compensating cylinder, full of liquid, having a piston with a spring behind it, connected to a larger bore of the plunger by a pipe, having a check valve in it. Whenever there is pressure in the plunger cylinder the check valve remains closed; but when the toggle is fully back, and the piston in the adjusting cylinder is against the cylinder head, so that no pressure due to its spring is exerted on the liquid, any loss of liquid will tend to create a vacuum in the plunger cylinder, and then the check valve will open and oil flow out of the compensating cylinder, under the pressure of the spring acting in its piston, to replace that lost.

Pneumatic Hammers.

We have been working on pneumatic hammers and we have now perfected a hammer in which there are one or two novel features.

In pneumatic hammers of nearly all makes, one of the sources of trouble has been that if the workman picked up the hammer and put his finger on the trigger when there was no chisel or rivet set in it, the piston would begin to reciprocate, and not having any tool to strike at the lower end, it would strike the cylinder head; and in a matter of a minute or two it would smash the piston or cylinder. About 75 or 80 per cent. of the breakages of pneumatic hammers are due to the carelessness of the workmen in pressing on the trigger when there is no work to do. In other words, the little piston strikes the cylinder head with disastrous results. We have devised a method of obviating this trouble that is very simple.

The admission port is located near, but not at the end, of the larger cylinder bore. When no tool is placed in the end of the hammer the lower end of the large piston diameter passes and closes the admission port, thus preventing air from acting upon the differential area to lift the piston. Any compressed air below the large diameter escapes by a small leakage port to the exhaust; and this leakage port is only open when the admission port is closed. In hammers actuated by valves exterior to the piston, it seems impossible to use this device, and attempts have been made to mechanically close such valves, but they do not appear to be very successful. The same effect is obtained, but at the expense of loss of air, when the leakage port is designed to open when the piston is at the extreme end of the stroke, but does close the admission port.

Patents are now pending for these improvements.

This very simple device is very effective. One can pick up a tool with 100 pounds air pressure in the pipe, put a finger on the button, opening the throttle, and it will not start unless the tool is fully in place, whereas, with all other tools I know of, the moment the trigger is pressed the tool begins to work, and would be useless in a few minutes.

Good wages come to the men that earn them—there are no exceptions.

Unique Ways of Doing Things in the Machine Shop—Readers' Ideas and Opinions Concerning Shop Practice—Useful Data for the Machinist. Remuneration Will be Given for Contributions.

PROPER METHOD OF BORING GAS-ENGINE CYLINDERS.

By Gordon A. Ronan.

Many are the methods devised by modern engine practice, to produce properly bored cylinders. To do this accurately, and at the same time economically, is not always easy.

The following article has been written with a view of assisting small manufacturers of gasoline engines, who are anxious to improve their present product, to whom the initial cost of a cylinder boring machine would be almost prohibitory.

Most small manufacturers pay too little heed to the essential features of their cylinders, which leads to trouble, when the engine is completed. A cylinder when finished should be bored absolutely cylindrical and parallel, the interior should present an even smooth surface, just as it leaves the tool. Under no circumstance should grinding with emery or other abrasive materials, take place.

To insure successful results, a builder of gasoline engines should have access to a well made engine lathe, of suitable size and proportions for work undertaken, the only other requisites being, one inexpensive cylinder jig pattern as shown in the accompanying cut, from which two castings should be taken, and a cutter-bar of the largest possible diameter, suitable to the bore and length of cylinder.

This cutter-bar should be made of machine steel turned its entire length, fitted with a cutter of circular section (see A in cut), inserted through cutter-bar leaving ample room for cylinder to clear itself at end of roughing cut. Three of these cutters should be used on each diameter cylinder required.

The cutters 1, 2, 3 should each in turn be placed in hole through boring bar, centrally located and each countersunk to accommodate a taper nosed binding screw. Cutter No. 1 is made first, the outer diameter is turned to the roughing diameter required, and is there backed off on either end to form two cutting edges, which should cut opposite the centre of the cylinder bore. The No. 2 cutter is formed in similar manner, only slightly larger in diameter, forming a lighter intermediate cut. The No. 3 cutter should receive the utmost care throughout its preparation. It should be about 1-10,000 inch over size. No. 2 cutter, and should leave the cylinder bored exactly the finished size. In the cut shown herewith 3.5 inches represents the bore.

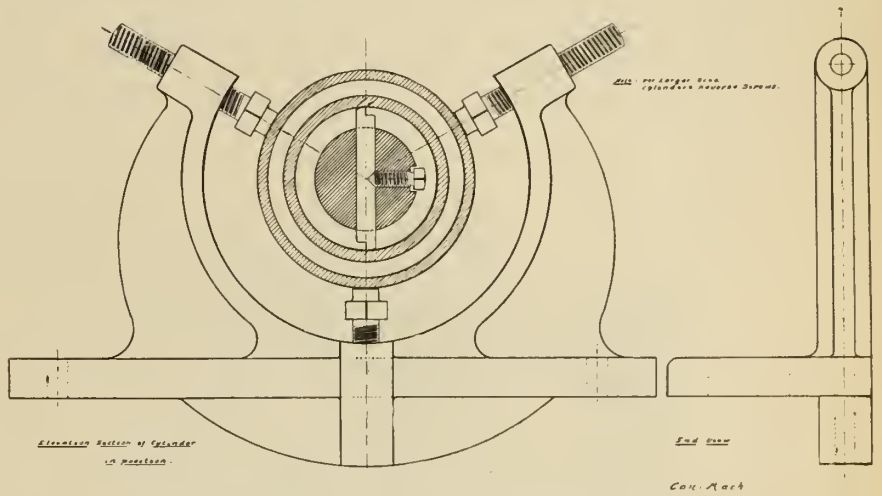
The jig pattern should be carefully planed on the bottom, and the three bases, which take the binding screws, should be perfectly square with the base. The jig should be securely bolted to the saddle of lathe, with one casting on either side of cross slide, by means of T bolts, size of lathe slots in saddle. In most lathes the jig can be slotted in such a manner as to admit a greater variation in length, thus admitting longer cylinders, and a greater range of work.

After the jig has been centred on saddle, by means of lathe centres, the cylinder is placed in position resting on the two lower binding screws, the boring-bar is next inserted through cylinder, placed between the centres and driven from the face plate by lathe dog. By means of this revolving cutter-bar, the cylinder is quickly centred and the six binding screws $\frac{5}{8}$-inch in diameter hold the cylinder securely in position.

The roughing cut is now taken with No. 1 cutter, which takes the heaviest feed and fastest speed the lathe will stand. Should a number of these cylinders be put through this first operation, it is advisable to lay the cylinders to one side for a day or so, to allow the molecules of the iron ample chance to regain their former position. If in haste, the second operation may be proceeded with, using cutter No. 2, with slower feed and speed. This is important, as a smoother surface will be made, so when cutter No. 3 is inserted only 1-10,000 of an inch has to be removed. This final cut should be taken very slowly and with a fine feed to insure a smooth, bright surface. The cutter should be carefully honed with oil-stone on the start. This leaves a surface void of ridges and the roughness so often found in so-called high-grade makes.

The cylinder, which up to this stage has not been removed from its position, has not been distorted, strained or forced out of shape in anyway, is now finished ready to be placed upon arbor, on which any later work on the exterior may be completed.

It is obvious with the jig presented herewith, many other similar classes of work such as pumps, bushings, may easily be done in like fashion, thus broadening the range of work and usefulness of this tool, making it an indespensable adjunct to every modern, up-to-date shop.



Proper Method for Boring Gas Engine Cylinders.

This method is not an experiment, but an actual success, having been found to operate very successfully in our experimental gasoline engine laboratory, and we recommend it to all our fellow-gasoline builders knowing that satisfactory results must follow.

ATTACHMENT AS DIVIDING HEAD.

By J. H. R., Hamilton.

I send you a sketch of a small attachment which could be placed on any lathe or similar machine to act as a dividing head.

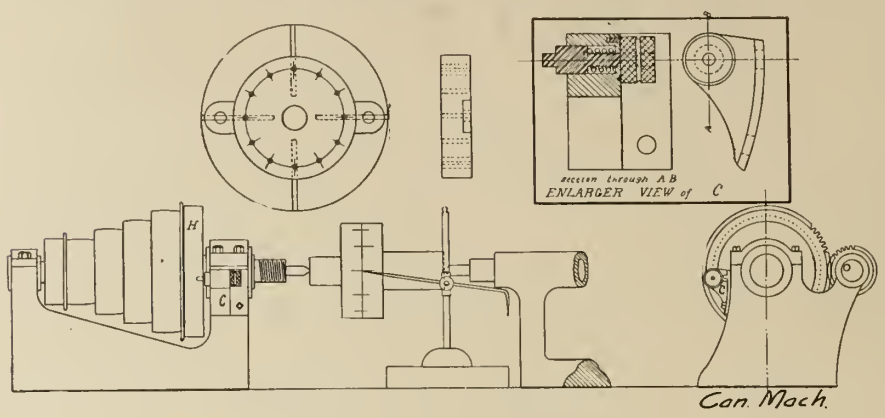
I have had occasion many times to

lay off equal distant holes on jigs, dies, etc., and finding the large gear H on most lathes were made with an odd number of teeth, it was necessary to scribe a circle and divide it into as many parts as is desired.

The accompanying sketch shows an appliance which could be used in many ways, such as laying of holes on a turned surface, as shown, or holding reamers in place while grinding clearance, and for many different odd jobs.

A graduated circle with an indicating finger would be very handy, but it would not lock the lathe head.

A circle divided into 72 parts would be very acceptable as a division of 2, 3, 4, 6, 8, 9, and 12, could be obtained. A circle could be scribed the desired diameter and a scriber in the tool post or a surface gauge could be used to divide the circle into as many parts as is desired.

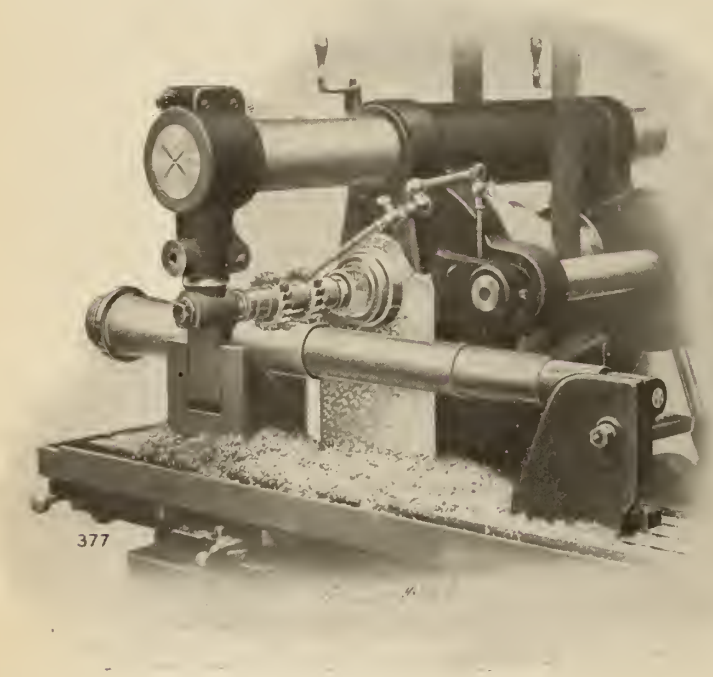


Attachment As Dividing Head.

MILLING KEY-SEATS.

By. C. S. Gingrich.

Every machine shop has some key-seating to do, and it is fast becoming the custom to consider this as distinctly milling machine work. One of the difficulties encountered in doing such work is the tendency of the machine to chatter. This is mainly due to the use of cutters poorly adapted for such work.



Milling Key Seats.

The accompanying illustration shows a key-seating job done on a No. 2 plain "Cincinnati" miller. The material is about 90 point carbon crucible steel, and the key-seat 13-16 in. wide x 3-8 in. deep is milled at a single cut with a 3½ in. diameter cutter running 44 r.p.m. with a feed of .075 in. per turn, giving a table travel of 3 1-3 in. per minute.

The second cutter shown on the arbor is for milling a part of this key-way slightly larger, so that the parts to which the key is fitted can be conveniently slipped into place.

The cutters, it will be noted, are "plain milling cutters." The teeth are spaced very wide (1⅝ in.) and although the cutters are only 13-16 in. face, the teeth are alternately nicked to break the chips. This is the form of milling cutter which has been demonstrated to cut the freest and the fastest.

It has been the practice in the past to use "side milling cutters," that is to say cutters with side teeth in addition to the peripheral teeth for such work. Experience has shown that such cutters are almost sure to chatter. A little thought will show that the side teeth are not needed, because all the cutting is done with the peripheral teeth. The chattering of side milling cutters can very often be materially reduced by reducing the angle of clearance on the side teeth. A better plan, however, is to not use such cutters at all for such work as key-seating, but use instead, cutters like those described above.

DATA ARRANGED IN HANDY FORM.

By J. H. R., Hamilton.

Herewith is shown a table of formulas and data, which is very often used by machinists and other mechanics, that I devised for ready reference, and which I have found very useful. I have taken off blue prints, which I have sold for 20 cents apiece. This table has met with such general favor that I thought it would be of interest to readers of Canadian Machinery. (Any readers desiring to secure a blue print of this table, can obtain J. H. R.'s name and address by sending us a postcard.—Editor.)

A SPECIAL RIVETER.

By Chester B. Albree.

Herewith is described a riveter built for some special work. The work to be done was the riveting of some concrete mixers, they being in the shape of two cones placed together. The problem was to reach into a very limited space and drive the rivets. It had been done by hand and something was wanted which would be a little quicker than the pneumatic hammer and something which would give tighter rivets, and be a power machine. It was necessary to have a reach of some 50 inches, and we had an extremely small opening. At the same time it was necessary to be able to adjust for different thicknesses of ma-

(2) MENSURATION.

In the following formulas, the letters have the meanings here given, unless otherwise stated.
D = larger diameter.
d = smaller diameter
R = radius corresponding to D.
r = radius corresponding to d
p = perimeter or circumference.
a = area of convex surface
S = area of entire surface = C + area of end or ends.
A = area of plain figure.
π = 3.1416 nearly, = ratio of any circumference to its diameter.
V = volume of solid.

Circle. (fig. 1.)

$p = \pi d = 3.1416\ d.$
$p = 2\pi r = 6.2832\ r.$
$d = \frac{p}{\pi} = \frac{p}{3.1416} = .3183\ p.$
$d = 2\sqrt{\frac{A}{\pi}} = 1.1284\sqrt{A}.$
$r = \sqrt{\frac{A}{\pi}} = .5642\sqrt{A}.$
$A = \frac{\pi d^2}{4} = .7854\ d^2.$
$A = \frac{pr}{2} = \frac{pd}{4}.$

Sector. (fig. 2.)

$A = \frac{1}{2}lr.$
$A = \frac{\pi r^2 E}{360} = .008727\,r^2 E.$
l = length of arc.

Segment. (fig. 3.)

$A = \frac{1}{2}l(r - c(r-h)).$
$A = \frac{r^2\pi E}{360} - \frac{1}{2}c(r-h).$
$l = \frac{\pi r E}{180} = .0175\,rE.$
$E = \frac{360\,l}{\pi r} = 57.2956\frac{l}{r}.$

Chord. (fig. 4.)

c = length of chord.
$r = \frac{c^2 + 4h^2}{8h} = \frac{c^2}{2d}$.
$c = 2\sqrt{2hr - h^2}$.
$l = \frac{8c - c}{3}$, approx.

Sphere. (fig 5.)

$S = \pi d^2 = 4\pi r^2 = 12.5664\ r^2.$
$V = \frac{4}{3}\pi d^3 = \frac{4}{3}\pi r^3 = .5236\ d^3.$

Ring. (fig. 6.)

$A = \frac{\pi}{4}(D^2 - d^2).$

Circular Ring. (fig 7.)

D = mean diameter
R = mean radius.
$S = 4\pi^2 Rr = 9.8696\,Dd$
$V = 2\pi^2 Rr^2 = 2.4674\,Dd^2.$

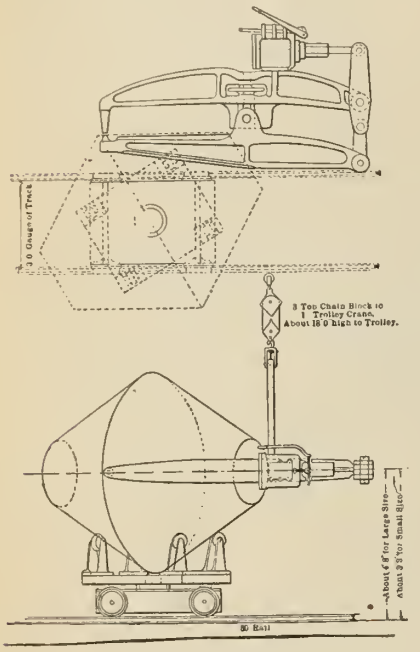
terial, and to give what we call an alligator motion to the jaws of the machine. The ordinary riveter could not be used for this work.

To secure adjustment of the projecting alligator jaws of the machine, we inserted a screw carrying the trunnions of the fulcrum on one end—a hand wheel with thread in the hub, serves to raise or lower the screw—thus adjusting the distance between the ends of the jaws as desired, and at the same time, not interfering with their clearance or action.

We also designed a special carriage to



Special Riveter for Riveting Concrete Mixer.

hold the double cones, rendering it unnecessary to raise either riveter or cones, but only to revolve the cones on their axis.

I might also mention a horizontal method of riveting boilers. We made a wheeled truck carrying on its bed three sets of rollers running in the opposite direction. We suspended from a trestle a riveter large enough to do boiler work, from a bail attached through a system of sheaves and tackles to a counterweight of one-fourth the weight of the riveter, and having four times the travel. Then all that was necessary to do was to have a small chain block on the trestle to overcome the friction of the sheaves and tackle. In that way we could raise this machine with a chain block for any diameter of boiler.

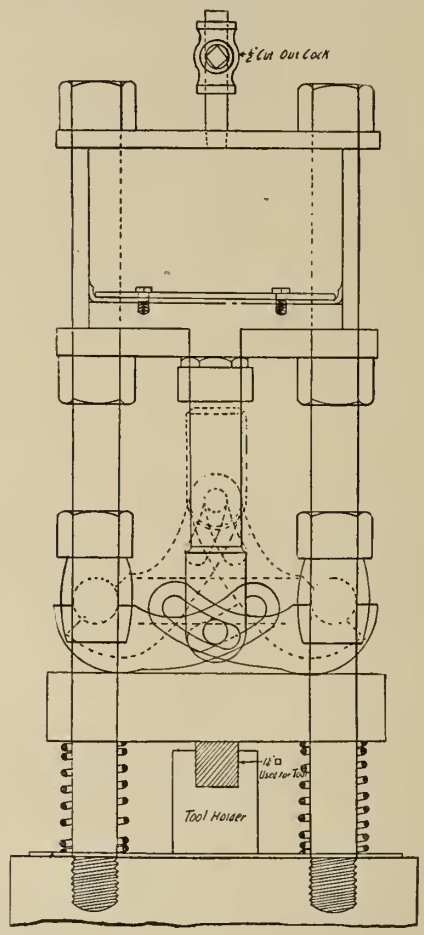
We have in very successful operation a machine with a ten-foot six-inch gap, weighing about 25,000 lbs. We are now installing several other machines of this character and it seemed to be quite a feasible plan. It has several advantages over the ordinary Tower system. It takes up very much less room and the initial cost of installing the plant is very much smaller. This system requires no hoisting of the boiler, as it is simply rolled on the floor or on the rollers. Thus the power plant of the machine is limited to that necessary to actuate the toggle.

JIG FOR DRILLING BRAKE SHOE HANGERS.

There is in use in the Toronto Railway shops a special jig which permits of drilling brake shoe hangers for eight different types of trucks. The device is here illustrated. By boring brake hangers in this device, absolute uniformity is secured, insuring correct hang of the brake shoes and consequent longer wear of shoes and wheels. The undrilled hanger is first drilled on one end, centred by the eye only. It is then placed in the jig and the pin inserted in the hole, governing the length required. By means of a set-screw at the back of the device, the hanger takes the correct position without further adjustment. The hole is then drilled, the drill being guided by a steel bushing.

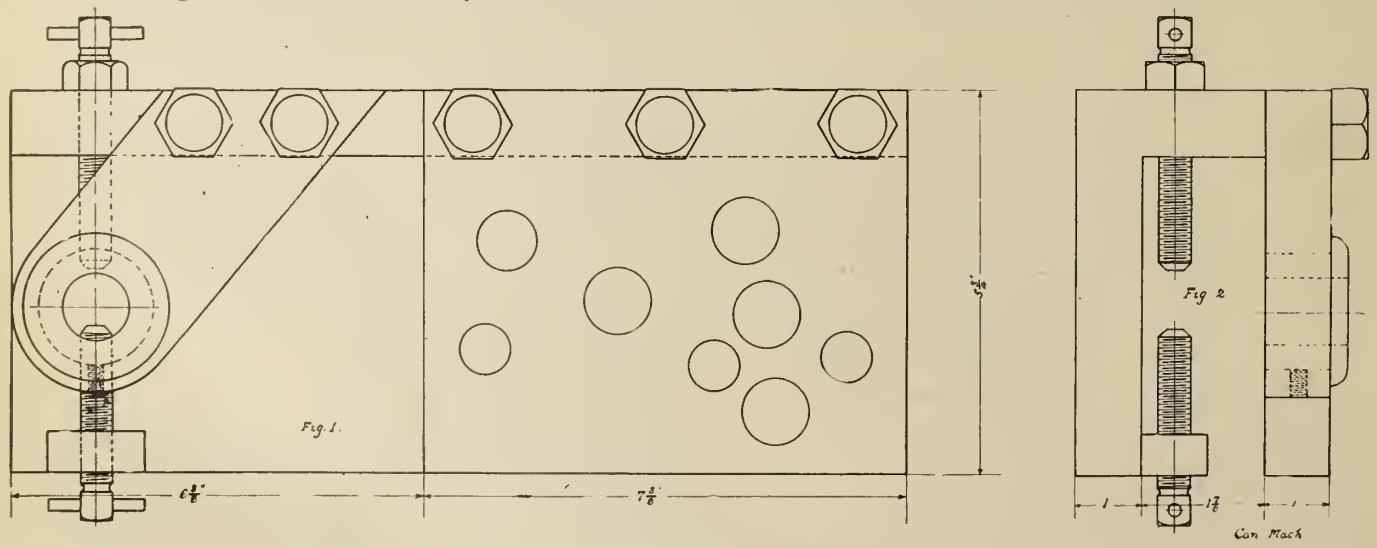
PNEUMATIC TOOL CLAMP FOR WHEEL LATHE.

The average wheel lathe man consumes from five to six minutes each time he changes tools, and as it is not



Pneumatic Tool for Wheel Lathe.

unusual to change five times for a pair of wheels, thirty minutes is used in the operation which is practically lost time. In order to reduce this time as much as



Jig for Drilling Brake Shoe Hangers.

possible, Mr. F. C. Pickard, machine foreman of the Pere Marquette shops at Grand Rapids, has devised a pneumatic appliance for raising and lowering the tool holder plate on a driving wheel lathe, to take the place of the usual four studs and nuts which are tightened with a wrench.

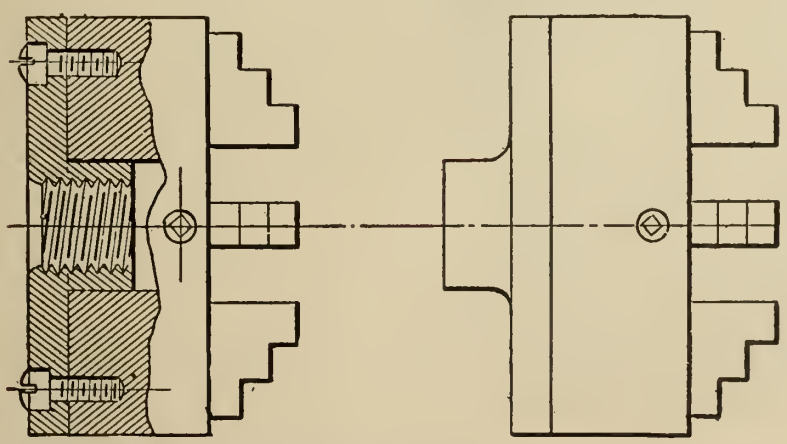
The device as shown by the illustration consists of a 7½ by 5¼-inch air cylinder, anchored by two stud bolts to the tool column, the piston operating two slotted cams which raise or lower the tool holder plate, according to the position of the piston. When the piston is down, the plate is forced against the tool, holding it firmly in position by air pressure, and when raised to the position as shown by the dotted lines the tool is released and can be freely removed. The coiled springs under the tool plate force it upward when pressure is released. The piston moves the tool holder plate ½-inch.

For a tool rest or holder, a piece of steel 2¼ by 3 inches is used and is slotted lengthwise along the top for receiving a piece of self-hardening steel 1¼ inch square. This not only saves steel, but gives a greater bearing on the tool rest.

By using this appliance, lathe tools can be changed easily in one minute without the exertion required in the usual method, and the trouble resulting from the wrench slipping and studs breaking is entirely avoided.—Modern Machinery.

IMPROVED METHOD OF FASTENING THE LATHE CHUCK TO THE FACEPLATE.

To the left of the cut is shown an improved method of fastening a lathe chuck to the faceplate instead of fastening it as shown to the right of the cut, which is the usual way. Two



Improved Method of Fastening the Lathe Chuck in the Face Plate.

important advantages are obtained by this change of method. The chuck will come nearer the bearing and a much stronger construction is possible. The method, as is plainly shown, consists of screwing the inside face of the faceplate to the chuck and allowing the hub to fit the inside of the chuck, the faceplate being finished all over and simply reversed from its usual position, which is to have the hub toward the lathe spindle and the face of the plate toward the chuck.—"Winamac," in Machinery.

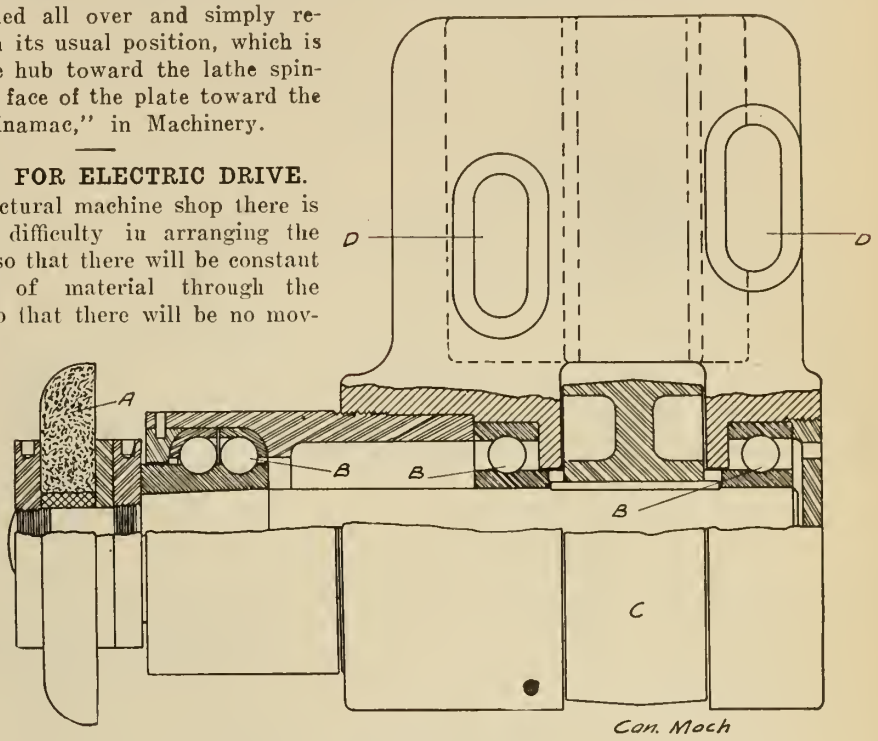
ONE USE FOR ELECTRIC DRIVE.

In a structural machine shop there is very great difficulty in arranging the machinery so that there will be constant progression of material through the shop and so that there will be no moving material over the same ground twice.

Thus in laying out a new shop there are mistakes made almost certainly, and the positions of machines have to be changed.

In view of this fact the Hamilton Bridge Works, Hamilton, have adopted a policy in connection with the extensions which they have made and are still making, which provides for just such contingencies, by driving all their machines, with individual motor, and instead of bolting the machines down to a permanent foundation, bolt them only to a wooden slab or something of like nature. Then, in case it is found advisable to change the position of a machine it can be done with the minimum amount of work.

They find that with electric drive such a foundation is quite firm enough.



Ball Bearing Grinding Spindle.

BALL-BEARING GRINDING SPINDLE.

By J. C. Armer.

The accompanying illustration is of a grinding head devised in the shops of the Chapman Double Ball-Bearing Co., Toronto, to replace the grinding head supplied with their grinder. They were persuaded that a ball-bearing would give better satisfaction for the high speeds they desired than an ordinary bearing, and designed the head as shown. It is giving excellent satisfaction. At A is shown the grinder; at B, B. B. are shown the bearings, showing clearly the balls and their runways; C is the driving pulley; and D, D, are slots for bolting the head to the grinding machine.

REVISED DUTY ON BRICK.

The Board of Customs has declared the rates of duties on the undermentioned articles as follows:

Fire brick (9-in.x4½-in.x2½-in.) valued at $10 and upwards per thousand at place of export, free under tariff item No. 281.

Pressed brick and other brick for building purposes, including fire brick valued at less than $10 per thousand at place of export—and stove linings manufactured from fire clay, are subject to duty under tariff item No. 282.

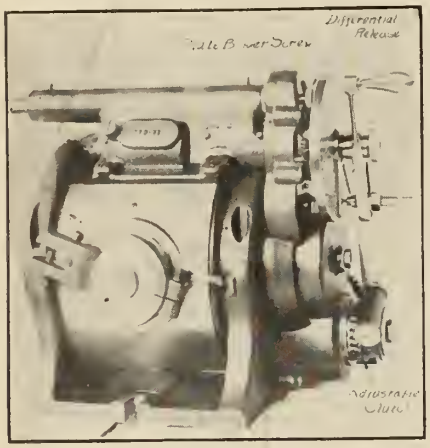
Developments in Machinery

Metal Working **Wood Working** **Power and Transmission**

THE UNIVERSAL INDEX AND SPIRAL HEAD.

This head is the result of a desire to fill the need of a spiral head that will at once answer the requirements of the heavier duty now imposed on the milling machine and still retain the fine points of accuracy expected from such a tool. In designing this head it has been the object to produce a design that would answer the requirements of the wide range of work met with in ordinary practice without sacrificing any of the desirable features of the older heads, and to add those features that good practice shows would greatly increase the usefulness of the head on general work.

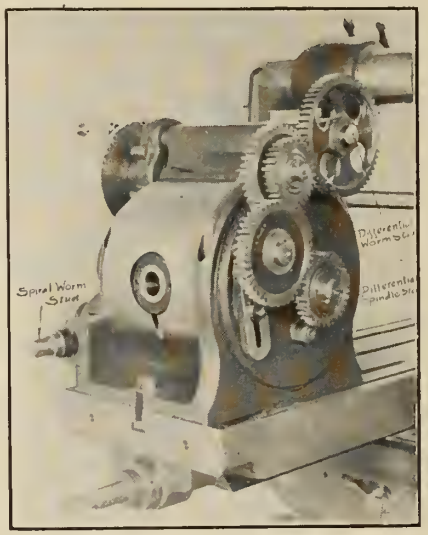
The worm gear is made in two sections so that one section may be rotated on the other to take up the wear on



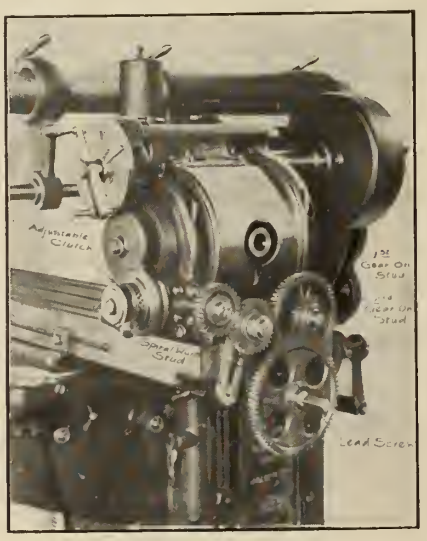
the teeth. This method has long been used and is the most accurate method of adjusting for wear and also in the hobbing of the teeth in the blank.

The stiffness and rigidity of the construction is shown plainly in the various views, This increase in strength has in no way impaired the ease of handling nor made the head at all clumsy or awkward to operate. The design is of an approved type, having the swivel block housed between heavy uprights in which the block swings in a vertical plane. The block is held in any position by means of clamping bolts which draw the outside plates securely against the uprights, making a secure bind, holding the head in position against the heaviest cuts.

The principal feature of the design is the large worm wheel that has been obtained. This gear has been made as large as the respective swing of each size head would allow and by the design followed it has been made much larger than that of any head so far offered.

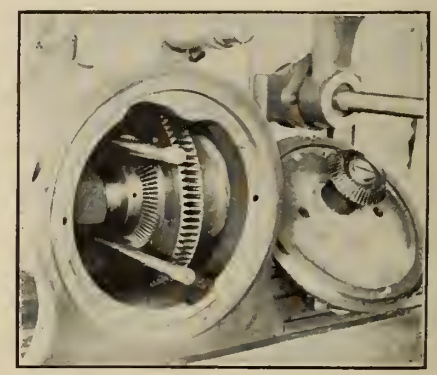


The view showing the back plate removed gives one a good impression of the extraordinary diameter of the dividing wheel. This large diameter adds much to the life of the wheel and insures greater accuracy in the work than would be possible with the smaller di-



ameter common to other dividing heads. The large diameter and resulting coarse pitch allows of much heavier spiral cuts being taken without the danger of impairing the accuracy, or of distorting the teeth in the gear. The increase of stiffness of the head in general makes possible the taking of much heavier cuts at faster feeds and speeds, obtaining the best possible results with high speed steels.

In bringing out this new head, the idea of making the differential indexing mechanism a component part of the head, has been carried out so that the head may be used as an index or dividing head in any position along the platen with the spindle either parallel with or at right angle to the main spindle of the machine, or in any intermediate position. This has been accomplished by placing the change gears used in differential indexing on the rear side of the head as shown in the view where the gears are set in position. As seen, the gears have no connection with the table at all as is the case with the



ordinary index head fitted for differential indexing.

With the gears used in differential indexing arranged on the head as is done on this head, it is possible to swing the spindle into position for cutting bevel gears or teeth on any conical work. This at once broadens the scope of differential indexing from straight cylindrical work to that which requires the angular setting of the spindle in the vertical plane.

In order that the application of the differential indexing may be universal, it is necessary that it be made available for use on work with helical or spiral grooves, such as spiral gears. It has been done in this new head. The manner in which it is accomplished is as follows :

The principle on which the differential system of indexing works, makes it

necessary to have the spindle and index plate so connected by means of change gearing, that the movement of the spindle will cause a movement of the index plate in one direction or the other as the case may be. This makes it necessary that the index plate be free to move on its axis independent of the index crank during the indexing operation. In cutting spirally the plate is geared to the lead screw by suitable change gears. The connection between lead screw and index plate must be broken when making the division in order that the index plate may be free to make the differential movement with the index crank. This breaking of the connection is accomplished by means of an adjustable clutch which is withdrawn during the indexing operation. After the division has been made, the teeth in the clutch will be found to be in such a position in relation to the corresponding spaces that it is impossible to engage same. In order to bring the teeth and spaces opposite each other, one half of the clutch is made adjustable so that it may be rotated the required amount to bring the two portions in proper position for engagement. This adjustment is accomplished by means of the knurled knobs attached to the clutch.

The connection between the index crank through the worm, worm gear, spindle and change gears of the differential indexing mechanism and the index plate when the index pin is in mesh with a hole in the plate would form a locked train, which must be released during the spiral cutting operation. This release is accomplished by means of the knurled knob back of the index plate, which operates a friction clutch.

Frequently it is desired to roll the work on its axis a small amount without shifting the dog or losing the position of the index pin or the amount of roll over may be so that should it be accomplished by rotating the crank, the pin would not come exactly over a hole as would be necessary. Should it be attempted to move both plate and crank in conjunction it would be found that the back pin of the ordinary head would not engage with a back hole. In this head the back pin is done away with and the plate is held in position when resorting to plain indexing by a frictional hold on the hub of the plate gear which is clamped or released by a suitable bolt conveniently located. By this means, work may be set regardless of the position of the plate, and the plate can then be securely held in the position it takes when the work is so set. All those who have used the ordinary head will realize the advantage to be gained in doing away with the back pin and substituting the more flexible holding device as is done in this head.

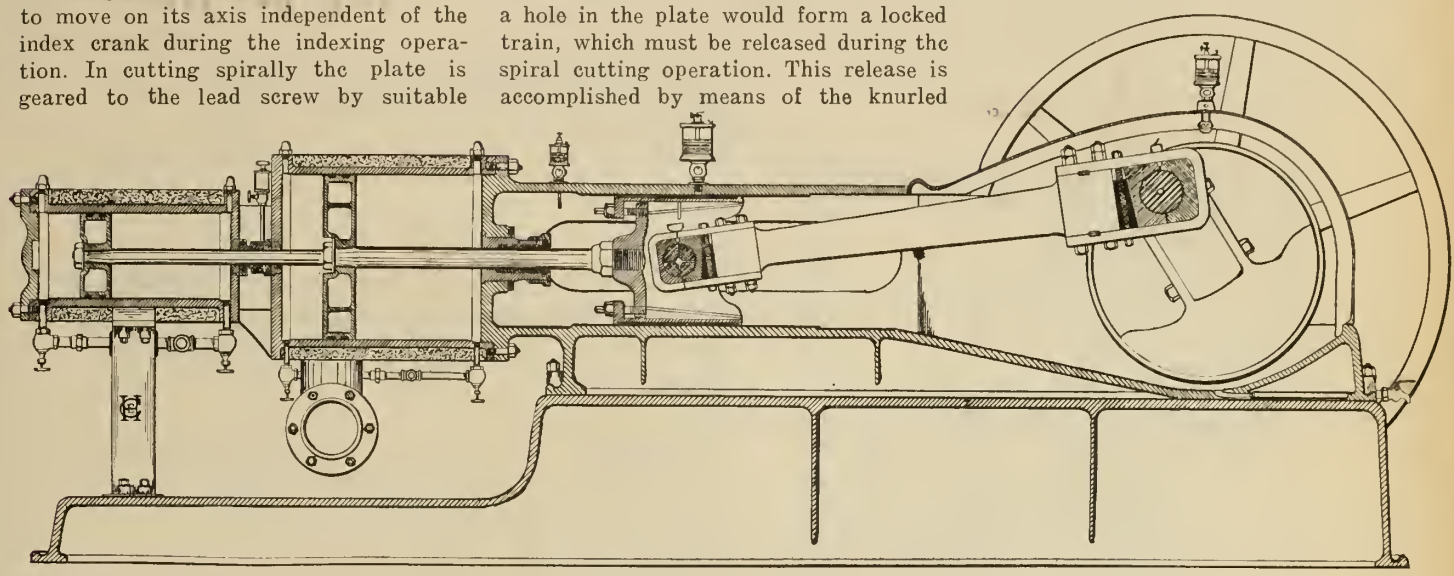


Fig. 1.—The Hardill Engine.

In work requiring the head to be connected up for spiral cutting, the roll over of work is made more convenient by the presence of the adjustable clutch, which, as explained above, allows the disconnection of the spiral cutting train so that the spindle and work may be revolved or rolled over without changing the position in relation to the cutter in a direction parallel with the feed motion.

This head is made by the Becker-Brainard Milling Machine Co., Hyde Park, Mass.

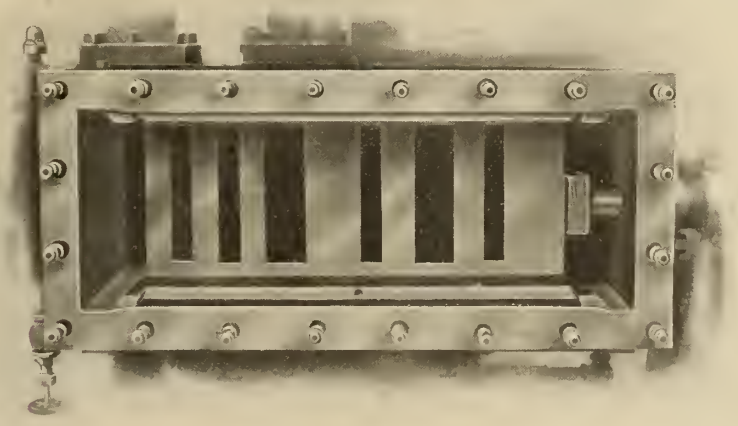

Fig. 2.—Valve Chest.

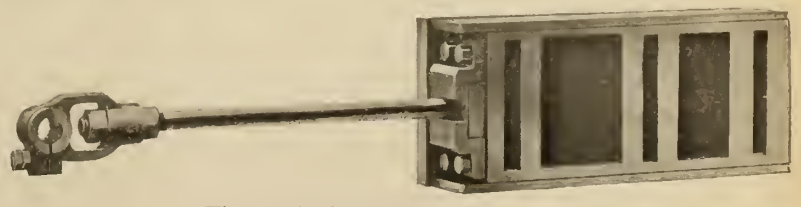

Fig. 3.—Valve and Rod.

Things don't just happen. They are the result of a universal fixed law. The good is the result of harmony and the ill is the result of discord—so get in harmony.

THE HARDILL COMPOUND ENGINE.

The engine which is herewith illustrated and described is a compound engine with some rather unique features which tend to simplicity of construction and steam economy. This engine was invented by Joseph Hardill some years ago, but since then he has been making improvements, and the one here described is the one which has just been completed. It is now being manufactured by the Berlin Foundry Co., Berlin, Ont.

A sectional view of the engine is shown in Fig. 1. The feature of the engine is that, although a compound engine, it is operated with a single slide valve and steam chest, shown in Fig. 2 and 3 respectively. The action of this valve can be seen from Fig. 3. In this view the cylinders are just taking live steam at the head end, the steam being admitted into the steam chest at (1), filling the space in the steam chest (2), and also behind the pressure plate (15). From thence we follow the steam by aid of the arrows and pass through the port (3) into the space (18) behind the small piston (5). Here the steam does its first work, forcing the piston forward; while the partly expanded steam of the previous stroke in the small cylinder at (4) is forced down through the port (6), through the passage in the valve (7), up into the space (9), behind the large piston (10). Here the steam again does work, and the thoroughly expanded steam in the large cylinder at (8), from the previous stroke, is passed down through the port (11), through the valve at (12), and thence out through the exhaust outlet at (13), and into the atmosphere or condenser.

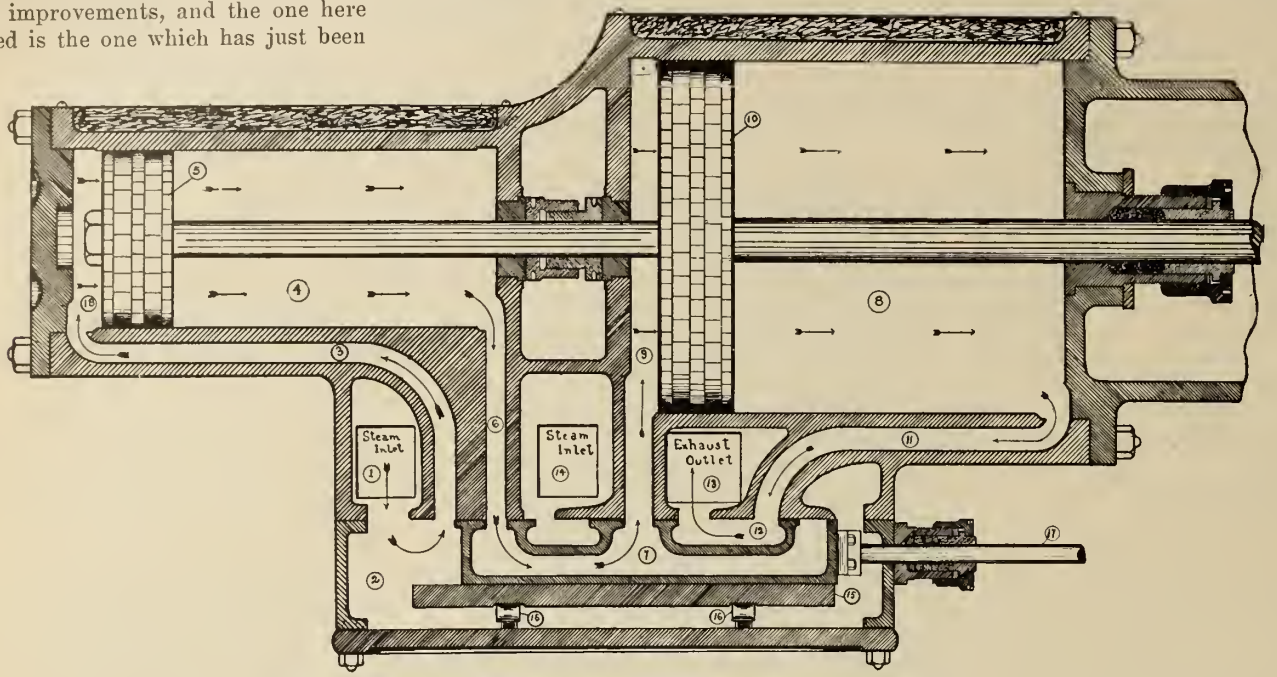

Fig. 4.—Sectional View of Cylinders, Steam Chest and Valve

In this way a complete cycle of operation for one stroke, the piston moving and the valve also in proper relation so that when the piston has reached the end of the stroke, the valve has moved so as to admit live steam from a second independent inlet at (14); and then the same cycle of operations is gone through for the return stroke.

That second independent inlet brings up a second distinctive feature of the engine, the operating valve, shown in Fig. 5. From this and from the other views it will be shown that there are two live steam openings (1) and (14). When the engine is operating on half-load or less, one of these openings can be closed by means of this valve, the operation of which is clearly shown in Fig. 5, thus making the engine a single acting engine. This prevents the necessity of the abnormal throttling of steam by the governor and throttling valve, which is one of the chief sources of loss of economy in throttling engines running under light load.

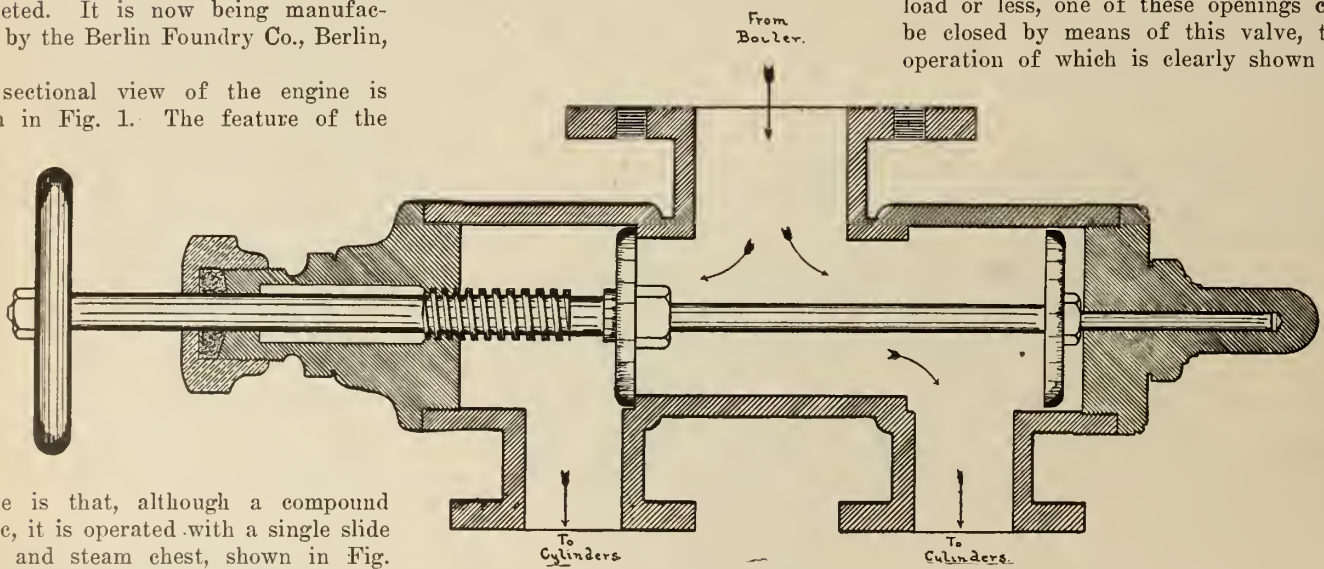

Fig. 5.—Sectional View of Control Valve

Thus, in this engine, the valve mechanism has been simplified, receiver or intermediate piping between cylinders

being done away with, and the abnormal throttling of steam is prevented under continuous light loads.

The general style of engine to which these new features have been attached is a self-contained centre crank engine of fairly high speed, 200 to 275 revolutions per minute.

Very low steam consumption is claimed for this engine, and favorable tests have been made on the engine by Prof. Nicholson and others.

NEW ADJUSTABLE REAMERS.

Accompanying is an illustration of the new adjustable reamer upon which the Lapointe Machine Tool Co., Hudson, Mass., have secured patents.

The blades of this reamer are made from half-round drawn steel, which can be obtained to the exact size, and does not require any machining to fit them to the body of the reamer, and permits the reamer to be made with interchangeable blades, which could not very well be done otherwise without enormous expense and accuracy in the machining of the blades. By taking the blades from stock as mentioned, it is only necessary to mill the top of the blade before fitting them into the reamer.

The grooves in the body of the reamer are first milled with a half-round cutter, after which the metal is pressed over. This, of course, is shown when the diameter of the body is left in the rough state about 1-16-inch over size, so that the same can be turned down to smooth surface. The collar is under cut so as to fit the end of the blades which are turned on a bevel. This has a tendeney to retain the blades in the bottom of the groove. The groove in the body is milled on an incline tapered to the front, which is an advantage,

New Adjustable Reamer.

thereby leaving more stock at threaded part, and also admitting a larger hole in the shell.

The most interesting feature of this reamer is, as stated before, that the blades can be made in large quantities, and, having grooves in the bodies closed up on the mastered blade, makes all the grooves of uniform size to admit in blades of the same radius. By this method the blades can be replaced when worn out without refitting, and will make it necessary to return the bodies of the reamers. The bodies of the reamers are made of machinery steel and the blades of highgrade carbon steel.

A "BLISS" DOUBLE SEAMER.

The double seaming machine illustrated has been recently built by the E. W. Bliss Company, 20 Adams St., Brooklyn, N.Y., and is especially designed for use in connection with the manufacture of large articles in ironware and enamelware, where the articles to be manufactured are round, such as foot tubs, wash tubs, buckets and similar articles.

The bottom or clamping plate is operated by toggles which respond to the action of the treadle and the treadle links. By depressing the treadle the toggles are locked and form a positive clamp between the chuck and body and allow the operator to take the foot pressure off the treadle. After double seaming is done the pressure is relieved by a slight movement of a handle on the right side of the machine, after which bottom plate drops to bottom position allowing article to be taken off and another placed in readiness for double seaming.

The adjustment for different heights of bodies is made by rack and pinion on left side, while adjustment for different diameters of articles and depth of seams is made by means of screws with hand wheels attached. One hand wheel can be seen in back of arm for operating double seaming roll while the one for adjusting for different heights of seams does not show in photo of machine illustrated. These adjustments are all easy of access and quickly made.

A point of note is the smoothing attachment on left hand side. In many articles the top edge of body is wired in a die and difficulty is often experienced, especially on tapering work, in making the metal hug the wire ring closely all the way round. With this attachment it is possible, while double seaming bottom, to smooth out the wrinkles formed in the process of wiring and roll the metal close to the wire and add considerable to the appearance of the finished article. This is also of advantage in enameling and galvanizing pails.

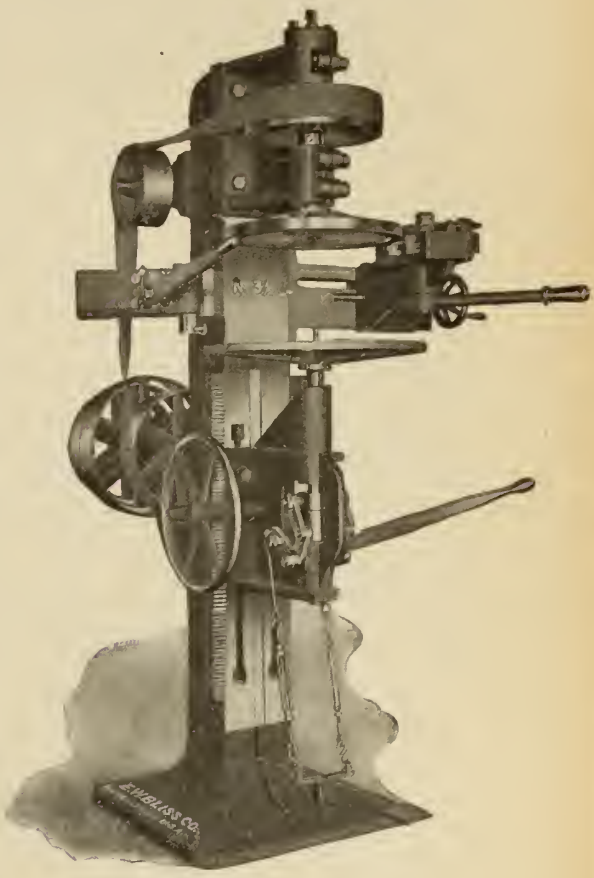
The machine will take work up to 26 inches in diameter and 36 inches in height and weighs about 3,000 pounds.

REPORT OF B.C. MINES.

The annual report of mining operations for gold, coal, etc., in British Columbia for the year ending December 31, 1906, has been issued by the minister of mines. Besides the detailed statistical tables and data concerning mineral production during the year, the report contains a large number of half-tone illustrations of mining centres, and picturesque spots in British Columbia.

Several very interesting curve sheets of mineral production during the years since 1858 are given.

In 1858 there was no platen gold mined; in 1863 there was a yield of



Bliss Double Seamer.

$3,900,000, the high water level; last year there was in the vicinity of $900,000.

The value of the coal mined has gradually increased from $50,000 in 1860 to $4,500,000 in 1906, although there have been some big fluctuations. The production of copper has shown a very big increase during 1905 and 1906, the value jumping from $4,600,000 to $8,250,000. The year 1894 was the first in which copper was taken out.

The mining of lode gold has seen a big increase since 1894, when it was $50,000. It reached the $4,900,000 mark in 1905, but dropped to $4,650,000 in 1906. Lead has seen wild fluctuations, reaching $2,700,000 in 1900, dropping to $750,000 in 1903, and rising again to $2,650,000 in 1906. There has also been a big variation in production of silver. In 1897, the value was $3,200,000; in 1899, it was $1,700,000; in 1901, it was $2,900,000; and in 1906 it was $1,900,000.

Foundry Practice

MODERN IDEAS FOR FOUNDRYMEN

Defects in Iron Castings*

Method Pursued in Ascertaining Defects in Locomotive Castings and the Remedies by which they were Overcome.

Robert Job.

Every manufacturer and user of iron from time to time meets with casting difficulties owing to defects in the iron, and in order to reduce fractures, discards and unsatisfactory service to the minimum, it is of great importance to know definitely the cause of the defects in order to apply the proper remedy.

In the course of everyday practice for many years, the writer has been interested in making a careful study of these matters as an aid in working out the most economical methods of manufacture and in securing the greatest efficiency in the output, and it may be of interest to give some details which have been observed from time to time.

Purchase of Iron.

In many foundries to-day, as was the case in one which first came under attention fifteen years ago, the practice is to purchase a number of different grades of iron—not by analysis, merely by brand—and to mix these in the cupola, with the object of obtaining special virtue from the combined properties of the metals. The underlying reason for this plan is simply that one brand runs high in silicon while another contains an excess of manganese, and still another is high in phosphorus making the iron very fluid, and very weak. The inherent defects of this method of mixing are well known to every foundryman, for difficulty is found in keeping up shipments of each of the different brands, and even when they are in stock, it is by no means an easy matter to get a correct mixture in the cupola even under the most favorable conditions. Consequently the foundryman is troubled by irregular quality of castings, and it is difficult to maintain proper control of the output, simply because there is great difference in the composition of the iron from day to day and even in different parts of the heat, when the intention has been to make a uniform grade of castings.

* Presented at the June meeting of the American Society for Testing Materials.

Variations in Composition.

Part of this variation is due to the difference in the composition of different lots of a given brand of iron. For example, we have known of different shipments of one brand which have ranged from 0.8 per cent. of phosphorus to 1.5 per cent. of phosphorus, while another showed an equal range in its manganese contents, and still another was varied from 2 to 5 per cent. in silicon. Under such conditions it is obviously out of the question to expect uniform results in the product, for at one time the iron is strong and tough, while soon afterward it is weak or brittle, or is full of blowholes and porous, and the foreman, who under the best of conditions, is none too free from troubles, finds himself in serious difficulty.

In order to secure uniformly good results it is obviously essential at the start to have in the finished casting a composition which will give the properties needed in service, and also adapted to the conditions of casting. Many service failures in the writer's experience have been caused directly by this neglect to obtain a uniform composition suited to the service. We remember particularly instances in which locomotive cylinders and wheel centres failed within a short time, and on investigation it was found that the proportion of phosphorus averaged nearly one per cent., while the silicon was over two and one-half per cent. As a result the iron was so weak that little tenacity under impact could have been expected, although the price paid for this grade was considerably higher than the market rate for quality far better adapted to the service.

In order to put a stop to these conditions under our own practice, a careful study was made to determine both the composition and physical condition and structure which gave the best service under different classes of requirements, and to determine the means necessary to secure this quality in the output.

In many cases of failure we found that the difficulty was due wholly, or in large part, to the presence of blowholes or to porosity or sponginess of the iron, and at times to the presence of considerable proportions of oxide of iron and cinder in the iron. Any of the latter conditions, of course, were direct indications of defective foundry practice, and where they existed defective composition was also often present.

In the daily routine of our foundry, general locomotive castings were made ranging in size from locomotive cylinders and wheel centres to small castings about one-quarter of an inch thick, and most of the castings required machining in some part. In view of this wide variation in size of and conditions of service, some doubt was felt whether a single grade of pig iron would meet the requirements. At the outset, however, we drew up specifications for a strong medium iron and upon receipt of each shipment, sampled and tested each carload before acceptance, to be certain that it was of the desired quality. The same practice was also adopted with reference to our coke supply, and the proportion of ash and of sulphur were held down to reasonable amounts. At the same time methods of treatment of the iron in the ladle and in the cupola were introduced to decrease hardness and to remove oxide of iron and blowholes, and to increase the fluidity and density of the iron.

Improvement in the Quality of Castings.

As a result of these changes excellent results were obtained from the very start. The single grade of iron with the careful control of the quality, gave a degree of uniformity which had never before been possible and by means of systematic treatment the properties of the iron could be varied as far as was desirable for the different purposes.

In the machine shops the change had an immediate effect, for hard castings, "porous iron" and blowholes almost entirely disappeared. Within a few months breakages in service had fallen off to a very marked extent owing to the toughening of the iron, and at the end of the year the scrap coming in was insufficient for the needs of the foundry. In order to keep track of the service, we stamped each wheel centre as it was cast, with the date,

and after a lapse of three years not a single one had been broken in service.

In the course of our routine work we found comparatively little difficulty in maintaining the desired quality in the shipments of the pig iron and the coke, though we soon learned that the systematic test of each carload of the raw materials was essential to insure proper quality of the product, for at one time a carload of weak iron would be kept from service, and at another time iron which would have produced hard and brittle castings. Still again, coke would not be accepted which proved to be deficient in heating value or was of such quality that hard castings would have resulted.

Cost of Pig Iron Decreased.

By means of the method of purchase under specifications the cost of the pig iron was decreased, and in the foundry the proportion of discards was cut down owing to the fluidity of the iron resulting from the cleansing of the metal from oxides and slag, and to the increased strength and toughness of the product.

From what has been said it will be evident that there is a definite cause for each of the defects which commonly cause difficulty in service or in the foundry, and it will be seen that these may be very largely removed by means of systematic control.

A PRINTLESS CORE.

By H. J. McCaslin.

As the name implies, it is a form of a dry sand core, which may be used in a mold without a core print setting, that is, it is located and attached to the pattern in its correct position as shown in two views in the accompanying illustration.

The fitness of the arrangement will be readily appreciated when coreing a series of holes at the bottom of a deep flange. Not only need the core be applied in this form, but it may assume various forms to suit the requirements and conditions.

When using this form of core, the pattern is placed within the flask and rammed up to that portion of the pattern which is to receive the core. This part of the pattern being provided with the slot or opening A, as shown, the core is set in place, and the ramming up of the pattern proceeded with.

It now only remains to draw the pattern from the core in the usual way, the core remaining in its rammed up position, and forming that part of the mold for which it was intended.

*The Steel Foundry as a Business Venture**

An interesting and instructive article, in view of the rapid strides steel castings are making for many purposes.

By W. M. Carr, New York.

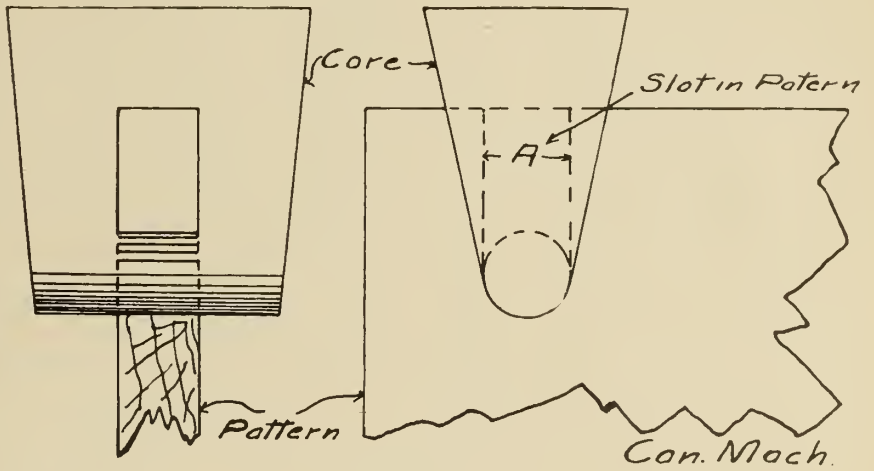
In recent years the steel casting industry has made rapid strides and for many purposes cast steel is gradually superseding cast iron. The situation is recognized by all engineers as one requiring the attention of leading and progressive cast iron founders. That the steel foundry business is an established industry is incontrovertible and one constantly improving and developing. The pioneers had their failures and losses but ultimate successes are obtainable, so that prospective investors in steel foundries will not have thorny paths to travel in order to get financial returns, as in the early days of the industry. The capitalist has better assurance of dividends than at any time in the past.

Capital.

The first question is : How much capital should be invested for a given output ? The answer cannot be particularized, because local conditions affect each individual problem, but the following remarks covering the subject broadly will serve as a guide to prospective investors :

Large tonnages of course yield large returns, but the net profit on a given amount of capital does not vary directly with the size of the plant. Small plants can show as great a percentage of profit as larger ones. The demand will largely control the size of the plant. To illustrate, we will consider a plant yielding 150 tons daily, or 4,000 tons monthly. Such a plant would employ about 1,800 hands, would require a large amount of ground with good shipping and receiving facilities. There should be at least five 25-ton open hearth furnaces, with four of them in regular operation. The furnaces would have to be served with electric charging machines, the molding and casting floors served by several 35-ton cranes. Hoists and light travelers would be required in cleaning, finishing and shipping departments. It should have a well equipped power house with engines and generators, pattern shop, machine shop, yard locomotives and liberal molding machine installations.

Such a plant as decribed could not well be started without $1,000,000 capital, and the cost of erection of suitable buildings with crane runways and complete equipment would amount to at least $750,000. The following estimate on the basis of ton capacity will cover plants varying from 80 tons per day with a two 25-ton furnace plant to one with five 25-ton furnaces producing 150 tons daily :



A Printless Core.

Furnaces only	$1,200
Gas producers, gas mains or oil tanks and accessories...	600
Buildings, 800 square feet per ton at $1.25.....	1,000
Power, machinery, cranes, hoists, ladles, drying ovens, etc	2,300
Total cost per ton.....	$5,100

Such an equipment with a good demand for casting can show 25 per cent. on the investment.

General Practice.

In general practice it is better to have two open-hearth furnaces if a modest plant is desired. Keep one in reserve in case the active one should go out of commission. The larger furnaces, 25-ton capacity, are best suited for heavy castings, although some plants run successfully on pieces averag-

* Presented at Philadelphia convention of American Foundrymen's Association.

ing 30 pounds each. A shop should be designed with a view to the character of work to be produced. If small work, pieces averaging ten pounds, a small open-hearth furnace is suitable.

Light Castings.

For very light castings, weighing ounces, the Tropenas process is in use, but it will not reachf the development promised by the open-hearth process producing basic steel castings. The pronounced limitations are the heavy losses and the high price of raw material. It is admitted by the inventor of the Tropenas process that the loss in melting is 17 per cent., a loss which in comparison with any open-hearth process is wasteful. In open-hearth practice the loss in melting only averages 7 per cent., and under favorable conditions a much smaller loss can be shown. The pig iron for the Tropenas process is imported and is of a special composition and is scarcely used for any other purpose. The pig iron for the basic process is cheap, domestic and plentiful in comparison, and, further, permits the use of almost any kind of steel scrap ; the latter material for a Tropenas vessel must be like the pig iron of special composition. The converter process is a comparatively new one and but very few operators can be found who are skilled. Investors who may place their money in Tropenas plants may find greater difficulties in their way than did the early users of the open-hearth processes, before commercial results can be obtained. The Tropenas process, however, is well suited for special purposes when certain kinds of steel are wanted in small quantities, but for general uses its own weaknesses are detrimental, preventing competition with open-hearth methods.

Basic or Acid Furnaces.

The question may arise as to whether an open-hearth plant should be fitted with basic or acid furnaces. The basic process is cheaper in the first place and the stock for it is more plentiful than for the acid. The chemical analyses of melting basic stock are wide and liberal. Those for the acid narrow and limited. The scrap for the basic process is almost only confined by its shape rather than its chemical composition. The scrap for the acid process is produced in the first instance by a basic process and will be represented by bloom ends, billet croppings, axle butts, plate clippings, etc., and is sold on analyses. It is stated that low phosphorous ores are getting scarce while high phosphorous ores are quite plentiful, so in regard to the material from which pig iron is made, the basic process has the greater promise. Physically basic steel in castings is just as reliable in every respect as acid steel.

Department for Gray Iron Foundries.

To the gray iron founder who feels the inroads of steel castings in his business and recognizes the demand, but is not disposed to invest a million dollars in a 150-ton plant, I would like to suggest to him the erection in his shop of an open-hearth furnace anywhere from two to ten tons in capacity. The furnace to be lined with a basic bottom and designed to burn either natural gas or fuel oil. Take as an average size one of five-tons capacity. Such would fit in ideally with existing equipment. Being basic, there would be no need of buying any fancy-priced imported stock ; any pig iron with silicon below 1.25 per cent., sulphur not over 0.08 per cent., and phosphorous with 1.00 per cent. or less can be used and such analyses would cover some grades of cast iron scrap in the shape of old car wheels, malleable, etc., and, charged with 50 per cent. of steel scrap, such as springs, rails, agricultural scrap, defective steel castings, etc., would give an opportunity to produce steel castings of good quality from low grade stock. Being of a moderate tonnage there would not be any heavy powered machinery to handle the heats. The only important change would be in regard to molding sand, a special grade being necessary. The basic furnace could be used to put to profit machine shop turnings and borings by mixing them in moderate quantities with the charges.

In some cases it might be advisable to line the furnace for acid melting and if desired it could be used for turning out " air-furnace-iron " heats.

Cost of a Small Furnace.

A five-ton furnace, basic lined, erected in an active iron foundry, would cost about $6,000, and allowing $4,000 for special bottom, pouring ladles, oil storage tanks, burners, etc., the total would be $10,000 exclusive of buildings. It would be capable of producing three heats daily and would yield 12¾ tons of castings at the rate of 15 per cent. in melting loss, gates, heads, skulls and defective castings, an average yield in a well ordered plant. Producing such tonnage steadily should show good profits. The single furnace however, has the advantage of going out of commission for repairs. It should turn out 400 heats before a general overhauling, or say a run of 133 working days. Assuming that the furnace was only productive nine months of a year at 25 working days per month, there would then be 225 days of yielding, a total output of 2,868¾ tons of product. Allowing an average profit of one-half cent per pound, there would be a gross profit of $28,687.50 annually.

But losses will arise in spite of best intention and not to make the venture look too roseate the set-backs will be considered which might be caused by breakdowns, strikes, or errors on practice. These conditions might reduce the good castings to one-half of the metal charged, so that 7½ tons were the output. With the same productive period of 225 days per year, and with a decided shrinkage, because of losses, between manufacturing costs and selling prices, so that the gross profit was only one-eighth cent per pound, the tonnage per year would be 1,687½ tons, and the returns therefrom $4,218.75. Out of this 25 per cent. can be deducted for interest on the investment, depreciation, etc., and there would remain a net profit of $3,164.07, which is equivalent to 31.6 per cent on the original $10,000.

The estimate in this case is very conservative and the low yield is an extreme. With careful practice the results can be made better than shown. There will be pitfalls and irregularities, but they will be greater in a large plane because greater units are concerned and heavier risks. The small furnace will be profitable as well as the large one, and should times be lean and the demand fall off, the small plant can bear the brunt as well as the bigger one because of the smaller amount of capital involved. There would not be in the small plant a top heavy organization to maintain or the demand for dividends to be met.

Profitable Investment.

A steel foundry in prosperous times is a good earner, but because it is a steel foundry with great possibilities, like any industry, it is not devoid of conditions of a negative character. An open-hearth plant with basic furnaces or acid furnaces does not have to pay patent royalties. The former type of furnace can take impure stock and refine it to steel. In that respect it has flexibility and a promising future. The acid process requires special composition stock of a limited nature in the market. The converter process requires skilled operators, hard to find ; has heavy melting losses, requires high-priced stock, differing some from open-hearth acid stock in composition. The crucible process does not refine, but simply remelts the product of the basic process in the shape of waste material. There are other evidences in favor of the basic open-hearth process as meeting the needs of a growing industry, and the foregoing points mentioned are to be taken into consideration when looking into the question of engaging in the manufacture of steel castings.

Where Should the Blame Rest? *

The question of "rat-tailing" is exasperating in foundries doing light work—Several assertions are made here as to the cause and cure.

By R. H. McDowell.

Among the troubles occurring in the foundry to-day, there are none so exasperating or, apparently, so hard to overcome as that known as "seaming" or "rat-tailing," which occurs so frequently in those branches of the foundry industry covered by the light plate molding, such as stoves and hollow-ware.

I have seen, in numerous instances, where the work in the foundry was coming out as smooth and perfect as was possible to make it; when suddenly, without warning or any apparent cause, dollars upon dollars, worth of casting will have to be thrown into the scrap as worthless, being covered with unsightly seams or ridges which make the castings unfit for the purpose for which they were intended.

Almost invariably the foreman goes after the molder with sword drawn. The molder strenuously insists that he is making his work exactly as he made it last week and the week before. Investigation begins. First it is blamed on the facing, and I have seen barrel after barrel of number one facing condemned in stove shops and shipped back to the dealer as "no good," because of this seaming on the face of stove castings; while the facts are that the facing had no more to do with this trouble than had the book-keeper in the office.

The next step usually taken is to make considerable of the work, on which they are having the most trouble, without any facing. The following day the work comes out of the mills with a rough, half-cleaned appearance and having the same unsightly "seams" on the surface. The fact that these seams appear when no facing was used carried no weight. The facing was pronounced "no good" and must go back.

As the facing question is settled and the "seams" continue to show on the castings, investigation starts anew. The sand is too wet, then too dry, and finally discarded as "no good." New sand is obtained; still the "seaming" goes on. The work is then poured with "hot" iron, then with "dead" iron. Every day new suggestions come up, new experiments are tried, and while these experiments are being tried the trouble generally disappears as it came, suddenly and without warning.

The foreman and the molder look at each other and wonder what they did to stop the seaming. If you ask them what caused the trouble, they generally say, "Oh! Our sand was burned out and we got into a batch of bad facing; but everything is all right now, we are getting in a new facing and have renewed our sand."

The cause of the trouble must be placed somewhere, and, not knowing where to place it, this is the easiest way out of it. "The facing and sand men are big fellows anyway, and can stand it."

In analyzing this trouble I am going to make four assertions, and I want those who are having this kind of trouble to watch and see if their experience will not bear out these assertions.

1. That where this trouble occurs, and disappears, the occurrence and disappearance always take place at a time when you start in on a new carload of coke or iron.

2. That when you are having trouble with "seaming" your iron is either hard and brittle, or if it is soft, you will find, on holding your face over a ladle of molten metal, you will almost be suffocated with the sulphur arising therefrom.

3. If you break a light casting, on which you have "seams," you willl find it either has the white appearance of iron high in combined carbon or sulphur, or a dead, cinder-like appearance of iron high in graphite carbon or free sulphur, with, perhaps, an excess of silicon in either case.

4. When you have a good grade of foundry iron, which to be good must of necessity be low in carbon, sulphur, phosphorus, and silicon, and melt the same with a good grade of coke, which must be low in sulphur and phosphorus, you will never be troubled with "seams."

When certain molders are turning out first-class work, day after day, with a certain grade of facing and sand, and suddenly it becomes impossible for the same molders, with the same material to make their molds, to make a good piece of work, reason should tell us that a radical change has taken place somewhere aside from the molding department.

As the only "elsewhere" about the foundry is the cupola, turn your experimenting in this direction, and, if you are sincere in your desire to know the right cause of this trouble, you will soon learn the facts and apply a remedy.

Space permitting, I would like to consider the cause of this trouble from a technical view-point, but if you who are having trouble in this respect will study carefully the above assertions and compare them with your own actual experience, I am satisfied that the results of your future experiments will be far more satisfactory; and when the "facing" and "sand" men come around again, you will greet them with a smile instead of a scowl.

* From the Obermayer Bulletin.

"SCRUFF" IN PIG IRON.

By T. N. Burman.

I wish to say a few words in your paper in regard to pig iron, and the mixture for gray iron castings for radiators and boilers. We have had about 25 years' experience in this line of work, and we have been troubled very much in the last few years with a dirty, spongy matter in the mixture, which, under the magnfiying glass, looks like a cinder. It runs with fluid iron, and stops in heavy places, and with us at such places as cross bars of a radiator section, and in boiler work at the rod holes or near the heavy hubs.

Now, a kind, old blast furnace superintendent gave me a name for this, "scruff." Now we all wish to get rid of this "scruff," for its presence costs any company who makes radiators and boilers a large pile of money. We test our boilers and radiators by the hydraulic test to the amount of 80 to 100 pounds, and this "scruff" is liable to make them leak under these tests. Once the "scruff" gets in the iron, it is difficult to get rid of it, and the only way is to pick out the iron which is the cause of the trouble in the yard before sending it to the cupolo. I am able now to pick these pieces out without fail. I have found that analysis does not tell all about the iron; and I wish to tell you something which may help you in getting rid of this "scruff," which, in my experience, is the worst trouble-maker we have had. I hope that some other brother foundryman will take up this same subject and tell us his experiences along this line.

Having a whole plant under my charge, I had a good chance to make tests. I made tests with different grades of coke, sands, blackening, and in the molding, but still we had the trouble. I cut out the "scruff" iron, and in a few heats we had no more trouble with leaks, and I proved to my own satisfaction that the trouble was not due to coke, blackening, sand or melting conditions.

Now, the way I find the pig iron with "scruff" in it is as follows: These pigs are usually covered with a dirty, rusty, spongy mass, and these I find to be the trouble-makers. There is another fact which may be interesting, which is, that the iron which shows very gray and brittle will give trouble when mixed with coke high in sulphur.

I hope that these lines will be of use to my fellow foundrymen.

AMONG THE SOCIETIES

SOCIETY OFFICERS.

Canadian Mining Institute.

President, George R. Smith, Thetford Mines, Quebec; secretary, H. Mortimer Lamb, Victoria, B.C.; treasurer, J. Stevenson Brown, Montreal.

Toronto Branch A. I. E. E.

Chairman, R. G. Black; vice-chairman, K. L. Aitken, secretary, R. T. McKeen.

National Association of Marine Engineers of Canada.

Grand president, Alex. L. De Martigny, Varennes, P.Q.; grand secretary, Neil J. Morrison, St. John, N.B.

Canadian Electrical Association.

President, R. G. Black, Toronto; vice-presidents, R. S. Kelch, Montreal, W. R. Ryerson, Niagara Falls, Ont.; secretary-treasurer, T. S. Young, Confederation Life Building, Toronto.

Canadian Association of Stationary Engineers.

President, Ed. Grandbois, Chatham; vice-president C. Kelly, Chatham; secretary, W. A. Crocket, Mt. Hamilton P.O., Ont.; Treasurer, A. M. Wickens, Toronto.

Canadian Railway Club.

President, W. D. Robb; secretary, James Powell, chief draughtsman motive power department, G. T. R.; treasurer, S. S. Underwood, chief draughtsman car department, G. T. R.

Engineers' Club of Toronto.

President, C. B. Smith; secretary, C. M. Canniff, 100 King Street W.; treasurer, John S. Fielding, 15 Toronto Street.

Canadian Society of Civil Engineers.

President, W. McLean Walbank; secretary-treasurer, C. H. McLeod, Rooms, 877 Dorchester street, Montreal.

Society of Chemical Industry.

Chairman, Prof. W. H. Ellis; vice-chairmen, H. H. Van Der Linde, Milton, and H. Hersey and A. McGill; hon.-secy., Alfred Burton, 44 York Street, Toronto.

Ontario Land Surveyors.

President, Thos. Fawcett, Niagara Falls; vice-pres., A. J. Van Nostrand, Toronto; secy.-treas., Capt. Killaly Gamble, Toronto.

STATIONARY ENGINEERS' CONVENTION.

At Guelph, on August 13, 14 and 15, the eighteenth convention of the Canadian Association of Stationary Engineers was held. The features of the convention included the reception by the civic authorities, business meetings, band concert in the park, trip to agricultural college and manufacturing plants in the city, and the banquet at which the city was represented by the mayor and several of the councilmen.

Opening Session.

After the civic reception on the 13th, the association got down to business, a few outstanding features being:

The new lodges since last convention are: Kingston, Petrolea, Windsor, London, St. Thomas and Stratford.

The secretary's and treasurer's reports showed the association to be in a splendid position, both financially and otherwise.

The following are the standing committees:

Legislative Committee—Messrs. Marr, Toronto; Clarke, Hamilton; Bean, Waterloo; Crocket, Hamilton; Bain, Toronto; Sansbury, Owen Sound; Scrimgeour, Stratford.

Mileage and Per Diem—Messrs. Moseley, Toronto; Bradt, Windsor; Grandboro, Chatham; Lyons, London; Johnston, Hamilton.

Good of Order—Messrs. Kelly, Chatham; Tait, Toronto; Day, Petrolea, Hegg, Guelph; McGhie, Toronto; Fowler, London; Borbridge, St. Thomas.

Auditors—Messrs. Noble, St. Thomas; Heathe, Hamiton; Gordon, Chatham.

Canadian Exhibitors' Association.

While the morning session of the 14th was in progress, the supply men and manufacturers' representatives formed the Canadian Exhibitors' Association, which is to look after the making of exhibits in conjunction with the conventions of the engineers. The officers are:

President—John T. Carlind, 36 Lombard St., Toronto.

1st Vice-president—Wm. Baird, Galt.

2nd Vice-president—H. W. Cook, 112 Bay St., Toronto.

Treasurer—Archibald W. Smith, Toronto.

Secretary—E. F. Heatherington, Galt.

Assistant Secretary—H. G. Fletcher, Toronto.

Papers and Speeches.

Papers presented included: Firing With Soft Coal, by Geo. D. Fowler; Is Electricity One of the Lost Arts? by W. A. Sweet, Hamilton; The Relation Between Publisher, Advertiser and Subscriber, by Arch. W. Smith, Engineering Journal, Toronto. Papers by W. A. Crocket and A. M. Wickens.

The address by Geo. D. Fowler is published in full in another part of this issue.

W. A. Sweet's paper was a humorous account of how it might be that electricity was known of and used in the days of Moses and Aaron.

Arch. W. Smith built up his address upon this fact: "In treating the subject of the relationship between publisher, advertiser and subscriber, it is assumed that advertising is an all-round paying proposition."

At the Banquet.

At the banquet, the secretary, W. A. Crocket, said that if manufacturers understood more thoroughly the aims and objects of the organization, they would give it more hearty support, and that they would give the association more help in its attempt to elevate the standing of the stationary engineer by providing means for better technical education and by getting the government to issue certificates.

A. M. Wickens claimed that in the case where steam was used for heating purposes that a good steam plant would prove more satisfactory and economical than producer gas plants or electric power; but he gave no figures in support of his argument. He thought that the manufacturer should pay more attention to the boiler and engine room and employ capable men so that there should be no waste of fuel by poor handling of plant. He should also give his engineer and fireman every encouragement in their efforts to improve themselves in knowledge.

Closing Session.

The closing session was taken up almost altogether in discussion of ways of improving and helping the association.

Earl Heatherington, of Goldie & McCulloch, Galt, was made honorary member of the association.

The new officers are as follows:

President—Edward Granbois, Chatham.

Vice-president—C. Kelly, Chatham.

Executive Secretary—W. A. Crocket, Mt. Hamilton P.O., Ont.

Executive Treasurer—A. M. Wickens, Toronto.

Conductor—Wm. McGhie, Toronto.

Door Keeper—Jos. Hegg, Guelph, Ont.

The next annual convention of the association will be held in Windsor.

Exhibits and Supply Men.

Among the manufacturers represented at the convention were: Goldie & McCulloch, Galt, by E. H. Heatherington; Waterous Engine Works; The Philip Carey Manufacturing Co., by H. M. Cook and H. E. Rowell; Dunlop Tire and Rubber Goods Co., by H. C. Austen; the Dearborn Drug and Chemical Works, Buffalo, by Jos. N. Gregory; The U. D. Anderson Co., Cleveland, O., steam traps, by L. H. Rumage; Albert E. Hawker, Toronto, steam traps; McLeod & Henry Co., Troy, W. H. Aderhold; The Electric Boiler Compound Co., Guelph; Frank L. Patterson & Co., Toronto.

ELECTRICAL CONVENTION.

The annual convention of the Canadian Electrical Association will be held in the rooms of the Canadian Society of Civil Engineers, 413 Dorchester St. W., Montreal, on Wednesday, Thursday and Friday, September 11, 12 and 13. This convention promises to be of unusual interest.

"N.A.S.E." CONVENTION.

The next annual convention of the National Association of Stationary Engineers will be held at Niagara Falls, N.Y., September 9 to 14. The meeting will be held in the Auditorium of the National Food Company's plant and at the Cataract House, and an entire floor of the plant mentioned will be devoted to exhibits of the machines, appliances and supplies used by steam engineers.

The National Exhibitors' Association, under whose auspices the exhibit is held, have arranged what is said to be a very elaborate program for the entertainment of delegates and visitors.

PERSONAL MENTION.

On July 31, P. E. Durst, President of the Canadian Steam Boiler Equipment Co., Ltd., Toronto, passed to the great beyond. His death came very suddenly, he being at business the day before in his usual good health.

J. Cecil Nuckols, for the past three years advertising manager of the S. Obermayer Co., Cincinnati, Chicago, Pittsburg, has recently received the additional appointment of advertising manager of the Cincinnati Electrical Tool Co.

Emil Hallman has but recently returned from an extended trip out to the Pacific Coast for H. W. Petrie. The trip turned out to be most successful. Mr. Hallman spent a good deal of his time this side of the Rockies, and also a good deal in the mining districts of British Columbia. Upon his return Mr. Hallman took a trip down to Cleveland and other American cities, visiting H. W. Petrie's American agencies.

T .B. Colborne, who has been connected with the Pond Machine Tool Co., and with Wm. Sellers, Inc., and who is late chief draftsman for the Ridgeway Machine Tool Co., Ridgeway, Pa., is now designer for the London Machine Tool Co., Hamilton. This is an indication of the progressiveness of the London Machine Tool Co. Mr. Colborne will bring many up-to-date ideas to his new work, and we may expect to see them brought out in the tools of the London Machine Tool Co. This company is to be congratulated upon securing the services of a man so well acquainted with the best machine tool practice in the United States.

TO GET THE BEST RESULTS.

In order to get the best results the following four conditions are necessary:

1 Complete and exact knowledge of the best way of doing the work, proper appliances and materials. 2. An instructor competent and willing to teach the workman how to make use of this information. 3. Wages for efficient work high enough to make a competent man feel that they are worth striving for. 4. A distinct loss in wages in case a certain degree of efficiency is not maintained.

These four conditions for efficient work were first enunciated by Fred W. Taylor, president of the American Society of Mechanical Engineers, and when they are understood their truth seems almost axiomatic. They are worthy of a very careful consideration. These conditions are really the steps that must be taken to get any piece of work done efficiently:

1. Learn how to do it right, and how long it should take. 2. Teach a workman to do it in the manner and time set. 3. Award the workman greater compensation for doing it in the manner and time set than he can ordinarily earn in any other manner. 4. Make the conditions of pay such that if he fails to do the work either in the manner or time set he gets only his day's pay.

LETTERS THAT PULL.

Here is some good advice given by Sherwin Cody, the authority on letter writing:

Letter writing is a distinct art, built principally on applied psychology. A good letter makes a sharp impression at the right place and at the right time. A bad letter lessens the impression that may have been created by a first and stronger one. Two weak letters following one strong one will make no impression whatever.

This is what Mr. Cody says:

;"Write a long letter to

"A farmer,

"A woman,

"A customer who has asked a question,

"A customer who is angry and needs quieting down and will be made only more angry if you seem to slight him.

"A man who is interested but must be convinced before he will buy your goods.

"Write a short letter to

"A business man,

"An indifferent man upon whom you want to make a sharp impression.

"A person who has written you about a trivial matter for which he cares little,

"A person who only needs the slightest reminder of something he has forgotten or of something he may have overlooked."—The Business Monthly Magazine.

ABOUT CATALOGUES.

BORING MILLS.—A circular issued by the Gisholt Machine Co., Madison, Wis., describing their 30 to 36-inch boring and turning mills. There are two 6x6 illustrations showing their standard types.

CRANES.—A booklet illustrating the hand-power and electric cranes manufactured by the Northern Engineering Works, Detroit. It is very neat throughout and the different types of cranes are shown up to good advantage.

TOOLS.—Catalogue No. 18 of the L. S. Starrett Co., Athol, Mass. A complete, neatly-arranged catalogue of all kinds of tools and measuring instruments. There are 230 pages 7x5 inches, with detailed illustrations and complete price lists.

GOULD & EBERHARDT'S SHAPERS.—A very handsomely illustrated catalogue of Gould & Eberhardt, Newark, N.J., about their shapers. This is a catalogue all interested in shapers should have, and they will be furnished upon application to the company.

MOTORS.—Circular No. 1118, issued by the Canadian Westinghouse Co., Hamilton, Ont., with descriptions and illustrations of their polyphase induction motors. It also contains a list of the circulars in force up to April, 1907, issued by this company.

PIPE CUTTING AND THREADING MACHINERY.—A catalogue gotten out by the Curtis and Curtis Co., Bridgeport, Conn., illustrating and giving price lists of the different hand and power cutting and threading machines manufactured by this firm.

FAN MOTORS.—A beautiful catalogue, issued by the Canadian Westinghouse Co., Ltd., Hamilton, Ont., describing with very clear and highly-colored illustrations, their different types of fan motors. The catalogue is of standard size, with a very pretty cover.

PULLEY BLOCKS.—A 40-page catalogue of the Steel Rope Pulley-Block Co., Sheffield, Eng., showing their different types of pulley-blocks, and emphasizing the exclusive features of each. They also show their chief cranes, hoists, and sheave blocks. It is well arranged and fully illustrated.

ARC LAMPS.—A booklet, of the Canadian Westinghouse Co., Hamilton, Ont., bringing out prominently the different points for consideration when purchasing arc lamps. It also contains a paper read by Brewer Griffin, before the Ohio Electric Light Association, which is interesting and instructive.

LIGHTNING TRANSFORMERS.—Bulletin No. 300 of the Allis-Chalmers-Bullock Co., giving a detailed description of the transformers made by them. Different sizes are shown and illustrated with elevations and cross sections. Several unassembled transformers are also shown, giving a clear idea of the parts.

GEAR CUTTING MACHINERY.—A very complete and handsome catalogue of Gould & Eberhardt, Newark, N.J., dealing with their automatic gear cutting machinery. The catalogue is 6x9 ins., and contains 60 pages. Illustrations are splendid, and information in detail. Company will send copies to anyone interested.

THE DWIGHT SLATE MACHINE CO.—A catalogue of machinery and machine tools manufactured by the Dwight Slate Machine Co., Hartford, Conn., including drills, automatic pinion cutters, marking machines, etc. It describes very fully every machine or tool, and also contains revised price lists of the different articles enumerated.

GOLDIE & McCULLOCH ENGINES.—Among the souvenir catalogues issued by Goldie & McCulloch, Galt, at convention of Canadian Association of Stationary Engineers was one of their "Ideal" high-speed engines. This catalogue is very handsomely gotten up, and the illustrating is excellent. A copy can be obtained by request to the company.

PNEUMATIC TOOLS.—An 80-page catalogue of the Independent Pneumatic Tool Co., Chicago, Ill., with cloth binding. The numerous pneumatic tools made by the company are shown in detail, and there are 30 photographs, showing the innumerable uses for them. The catalogue is arranged with the greatest taste and is indeed a credit to the company.

LIFTING MAGNETS.—A circular issued by the Cutler-Cammer Clutch Co., Milwaukee, Wis., describing their lifting magnets and claiming superior features for them. The circular is accompanied by eight photographs showing the different types of magnets in different uses. These cuts give a good idea of the many uses to which these magnets can be put.

Industrial Progress

CANADIAN MACHINERY will be pleased to receive, as confidential, industrial news of any description, the incorporation of companies, establishment or enlargement of plants, railway, mining or municipal news.

News Plants and Additions.

The town of Woodstock, N.B., suffered by fire.

The Mitchell Electric and Machinery Co., Winnipeg, is insolvent.

The Alberta Biscuit Co. will erect a factory in Edmonton, Alta.

T. Lawson will erect a blacksmith shop in Ottawa, to cost $2,000.

The St. Clair foundry, in Preston Springs, Ont., is being enlarged.

The Doty Engine Co., Goderich, Ont., are erecting a new foundry.

Fire did damage to the town of Oxbow, Sask., to the extent of $175,000.

The Hanbury Mfg. Co. will erect a factory at Brandon, to cost $4,500.

The Brandon Mfg. Co. will erect a factory in that city to cost $2,000.

Moose Jaw is in need of an addition to its power and lighting plant.

W. C. Edwards' sash and door factory, Ottawa, was destroyed by fire.

Smith, Runciman & Co., Toronto, will erect a warehouse to cost $45,000.

Williams & Wilson, Montreal, are erecting an addition to their warehouse.

The Hull Electric Co., Hull, Que., are erecting an addition to their plant.

The Canada Steel Goods Co., Hamilton, will erect a factory to cost $75,000.

The Ontario Iron and Steel Co., Welland, will begin smelting operations soon.

The stock of the Fruitland Brick & Supply Co., Fruitland, Ont., is for sale.

The assets of the Good Roads Machinery Co., Hamilton, are advertised for sale.

Fire damaged the Flemming foundry, St. John, N.B., to the extent of $1,000.

The Guelph Spring and Axle Co., Guelph, are making an addition to their works.

The Canadian branch of the Royal Mint will cost, when completed, about $500,000.

The Hawes-Yougol Mfg. Co., New York, are looking for a site in Brantford, Ont.

The Chestnut Canoe Co., Fredericton, N.B., are erecting a factory to cost $13,000.

A. I. Isaac's cigar factory at St. John, N. B., was destroyed by fire; loss, $4,000.

The H. H. Dryden Co., Sussex, N.B., will considerably enlarge their tinware plant.

The Massey-Harris Co. will erect a large factory at Brantford, Ont., to cost $20,000.

An American brass manufacturing concern are anxious to obtain a site in Sarnia, Ont.

The Western Bag Co., Winnipeg, will erect a warehouse to cost $200,000 in that city.

The Canadian Cutlery Co. want a loan of $25,000 to erect a plant at Grimsby, Ont.

The Brantford Linen Mfg. Co. are going to transfer their factory to Tillsonburg, Ont.

The planing mill owned by Geo. Wood & Son, Dundalk, Ont., was destroyed by fire.

The sash and door factory of Henry Henks, Toronto, was destroyed by fire; loss, $6,000.

A gasoline engine and cream separator manufacturing concern may locate in Chatham, Ont.

An Illinois concern may erect a factory at Edmonton for the manufacturing of furniture.

The sash and door factory of V. E. Traversy, Montreal, was destroyed by fire; loss, $20,000.

R. T. Godman, Vancouver, B.C., will erect a mill between Point Atkinson and the Narrows.

The Superior Oil Co., Sault Ste. Marie, Ont., suffered damage by fire to the extent of $1,200.

The buildings of the Manitoba Peat Works, Fort Francis, Man., will be rebuilt immediately.

The Bloomfield Packing Co. will erect a large canning factory at Hillier, Ont., costing $25,000.

The Canadian Bag Co., Winnipeg, will erect a new bag factory in that city, to cost $10,000.

A firm manufacturing heaters, stoves and furnaces is anxious to obtain a site in Sarnia, Ont.

H. Proctor and C. W. Hughes, Toronto, have formed a contracting firm in Fort William, Ont.

A large boiler works will be established at Halifax, N.S.

The Canada Woodenware Co. have been offered strong inducements to locate in Chatham, N.B.

The Cobalt Concentrators, Ltd., are asking for tenders for a concentrating mill at Cobalt.

The Dominion Car and Foundry Co., Montreal, will enlarge their works at a cost of $2,000.

The Dominion Paint Co.'s premises at Hamilton were damaged by fire to the extent of $1,200.

The storage tank of the Imperial Oil Co., at Sarnia, Ont., was destroyed by lightning recently.

The factory of the Dominion Furniture Co., St. Therese, Que., was destroyed by fire; loss, $100,000.

The International Turpentine Co. will install a plant in New Westminster, B.C., to cost $30,000.

The North American Timber Co., St. Paul, Minn., will erect six large sawmills in British Columbia.

The Canadian Shovel & Tool Co., Hamilton, Ont., will erect an addition to their plant, to cost $1,000.

The Adams River Lumber Co., Shuswap, B. C., will erect a large sawmill on Little Shuswap Lake.

The Toronto Bolt & Forging Co., Swansea, will erect a plant at their present works, to cost $30,000.

The Great Northern Supply Co., Swift Current, Sask., are putting up a new block, to cost $20,000.

Work has commenced on the erection of the steel plant of the Coughlan Company, at Vancouver, B.C.

A firm manufacturing stoves for burning soft coal wants a free site and loan of $10,000 from Sarnia, Ont.

The Kensington Furniture Co., Goderich, Ont., are making extensive additions to their furniture factory.

The pumping plant at Well 5 of Fort William's waterworks system was destroyed by fire; loss, $12,000.

A company has been formed for making cast iron culverts and will establish a plant in Port Arthur, Ont.

The Miramichi Lumber Company are negotiating for the purchase of the Clark Spool Mill, Newcastle, N.B.

The Delaware Seamless Tube Co., Reading, Pa., may build a large plant at Sarnia, Ont., to cost $200,000.

The Canadian Machine Telephone Co. will erect a building in Brantford for their automatic exchange.

The British Columbia Electric Co. suffered damage to the extent of $1,000 in the recent fire at Victoria.

The Otis-Fensom Elevator Co. will build a branch for British Columbia at Vancouver, B. C., to cost $35,000.

A new steam heating plant and ventilating system is to be installed in St. Joseph's hospital, Guelph, Ont.

The shingle mill of the Valley Shingle Co., at Padden, B.C., was destroyed by fire, entailing a loss of $7,000.

The Canadian Pin Co., a new concern, will erect a factory at Woodstock, Ont., for the manufacture of pins.

Pressed Bricks, Limited, are anxious to obtain a site in Strathcona, Alta. They want an exemption from taxes.

An electric power plant may be established at Medicine Hat to operate the C.P.R. works and the pusher engines.

The pulp and wood mills of the North River Lumber Co., Murray, N.S., were totally destroyed by fire recently.

The Ladysmith Lumber Company will erect a saw mill near Nanaimo, B.C., to cut 35,000 feet of lumber per day.

The Ottawa Steel Casting Co., Ottawa, will increase the capacity of their furnace to 8 tons per day. A new addition will be erected and a new plant installed.

The representatives of the Ross Oscillating Pump are in Calgary looking for a purchaser for the Canadian rights.

A large American firm manufacturing agricultural implements will make their western headquarters at Regina, Sask.

A brick company has been formed by some residents of Lacombe, Alta., and a large industry will be established.

The Victor Wood Works, Co., Amherst, N.S., have gone into liquidation. The Maritime Heating Co. have also failed.

The saw and shingle mills of the Miller & Seim firm at Hampden, Ont., were destroyed by fire recently; loss, $7,000.

The Jackson Wagon Works, Galt, have been purchased by D. Clement, Ayton, Ont., who will erect a sawmill there.

The plant of the Midland Engine Works is again in operation. The capacity of the molding room has been doubled.

Work has commenced on the factory of the Aluminium and Crown Stopper Co., Toronto. The factory will cost $50,000.

Hamilton purchasers have acquired the timber limits, mill, and machinery of McManus & McKelvie, New Liskeard, Ont.

J. Davidson, Millbrook, Ont., has purchased the lighting plant and has been awarded the contract for lighting the town.

The huge steam engine in the Ogilvie Flour Mills, Winnipeg, has been replaced by an electric motor of 1,200 horse-power.

Gates & Carpenter, of Salt Lake City, were in Haileybury. They propose the erection of a large smelter there, to cost $6,000,000.

The cement brick works at Radisson, Sask., have started operations and the product has been found satisfactory in every way.

The W. P. Demond Upholstering Co. wants to secure a loan of $12,000 and free water, before erecting a plant in Strathroy, Ont.

The saw mill and woodworking factory belonging to J. H. Simonson, at Sprague Mills, N.B., was destroyed by fire; loss, $10,000.

The saw mill and assets of the Manitoba Lumber Co., at Eburne, Man., have been purchased by P. D. Roe, Port Moody, Man.

The Rogers Mfg. Co., Kansas City, will erect a large plant at Strathroy, Ont., and manufacture malleable iron and journal boxes.

There is a chance of a large cut glass manufacturing concern being established at London, Ont. Mr. Wm. Gray is at the back of it.

The machinery is being installed in the new buildings of the St. Thomas Canning Co., St. Thomas, and will be running in three weeks.

The Union Lumber Co. has been incorporated in Edmonton to supply lumber to union men at a little above cost. The capital is $250,000.

R. Forbes Co., Hespeler, Ont., has secured a Dominion charter and will manufacture textile goods. The capital of the company is $1,000,000.

The Eells Lime Co., at Rockport, N.B., and the Rockport Ice Co., suffered heavily by fire recently. The damage was estimated at $75,000.

The Ryan Storm Canopy Co., Sault Ste. Marie, want to locate in Western Ontario and ask a free site and a loan of $15,000 for two years.

W. J. Campbell, Ottawa, will erect a boiler works in that city, to cost $20,000. A new bridge will be erected at Lac du Bonnett, to cost $40,000.

The W. C. Edwards Co., Ottawa, will immediately commence the erection of their mill, which was destroyed by fire. The new mill will cost $300,000.

The barns of the Southwestern Traction Co., London, Ont., were destroyed by fire, with twenty valuable motors. The total loss was about $150,000.

A large iron and steel plant will be constructed at Kootenay, B.C. Construction will commence shortly, and the initial expenditure will be $2,500,000.

The Rocky Mountain Cement Co., Toronto, will receive tenders for engines, boilers, mills, etc., to cost $90,300. E. H. Keating is the managing director.

The buildings of the new plant of Jenkins Bros., Montreal, have been completed, and the

machinery is being installed. They will make valves of all kinds.

The work of building the plant of the cement works in Welland, Ont., is progressing rapidly. The buildings will be completed by the end of the year.

The first installment of machinery for the new pulp mill of the Gordon Paper Co., Dryden, Ont., is on the ground and installation will commence immediately.

The Library Bureau, of Ottawa, will not rebuild their factory on the old site, but will move to another part of the town, where a modern plant will be erected.

H. New, Hamilton, will form a company and manufacture vitrified brick and other materials. A modern plant will be erected and a high grade product will be turned out.

The Chapman Double Ball Bearing Co., Toronto, have been awarded the contract for the entire equipment of the new plant of the Standard Fitting & Valve Co., Guelph.

Negotiations are going on for the purchase of the Ottawa Electric Railway, the Ottawa Electric Light Co., and the Ottawa Gas Co. American capitalists are interested.

The International Heating and Lighting Co. have obtained a franchise from Fort Saskatchewan, and will erect a plant there. Machinery has been ordered, to cost $100,000.

The Northumberland-Durham Power Co. are considering transmitting power from Healey Falls to Deseronto and Kingston, and plans for the transmission lines are being prepared.

Fox & Co., mantel and woodwork manufacturers, will erect a factory in Windsor, Ont., to cost $40,000, if the city will give them exemption from taxation and free light and water.

The large plant of the Red Cliff Brick Co., near Medicine Hat, is in full operation. The plant cost $100,000, and will turn out 60,000 bricks a day. This number will be rapidly increased.

The Eadie-Douglas Co., Montreal, have been appointed Canadian agents for the waterproofing for concrete, plaster, wood, steel and iron manufactured by the Preservating Products Co., New York.

The North American Bent Chair Co., Owen Sound, Ont., have awarded the contract to the Dominion Heating and Ventilating Co., Hespeler, Ont., for an extensive shaving handling system.

An experiment is going on in Medicine Hat with natural gas. It is proposed to compress it in tanks and sell it for use in place of gasoline. It is claimed to bevery much cheaper and easier to handle.

The Uxbridge Organ and Piano Co., Uxbridge, Ont., suffered severely by fire recently. The building in which the greater part of their machinery was kept, was destroyed by fire, entailing a loss of $25,000.

The contract for the construction of the power house of the Sydney and Glace Bay Railways at Dominion No. 4 has been let to Rhodes, Curry & Co., Amherst. The plant and machinery will cost $25,000.

The Dominion Car & Foundry Co., Montreal, will erect a large addition to their plant, to cost $2,000,000. A cast steel plant will cost $1,000,000, and a malleable iron plant and three steel car works will be erected.

The Schaake Machine Co., New Westminster, B.C., have secured the right to manufacture and sell a line of lath machines manufactured on a large scale by the Bolton Lath & Shingle Machinery Co., Minneapolis, Minn.

The Canadian Fairbanks Co. have just completed the installation of machinery, including a 6 h.p. gasoline engine, for a 20,000 grain elevator of the Canada Grain Co., Beaton, Ont. This work was in charge of T. W. Ellis.

The North Arm Lumber Co. Vancouver, obtained a very suitable mill site and will at once erect a mill, at a cost of $150,000. The machinery has been ordered and the mill will be in running order about the beginning of the year.

The Beach Mfg. Co., manufacturing the Beach Triple Expansion Engine and Cast Iron Culverts, are anxious to locate in Port Arthur, Ont., and want a free site and twenty-five per cent. of capital subscribed. The proposed capital is $100,000.

A company to be known as the Monitor Manufacturing Co., has been formed in Fredericton, N.B. The company will manufacture the Monitor Acetylene Generator. The capital of the company is $25,000. They have secured a site and will begin operations immediately. Lighting plants of all sizes will be manufactured.

The fifteenth annual meeting of the shareholders of the Page Wire Fence Co. was held recently. The year's report showed an enormous increase, the volume of sales being the largest in the history of the company. The officers were all re-elected as follows: President, Walter Clement; vice-president, N. L. Clement; secretary-treasurer, Merton Church.

The Smart-Turner Machine Co., Hamilton, are supplying the following with standard duplex pumps: The Hamilton asylum, the Temiscaming & Northern Ontario Railway, the Exeter Canning and Preserving Co., Exeter, Ont.; the Canadian Canners, Leamington, Ont. The Lehigh Portland Cement Co., Allentown, Pa., have ordered three duplex plunger pumps.

Companies Incorporated.

The Peterborough Boiler and Radiator Co. has changed its name to Canadian Boiler and Radiator Co.

McEwen Bros., New York; capital, $25,000; have secured an Ontario license and will make and deal in steam engines and machinery fittings.

The Watford Milling Co., Watford, Ont.; capital, $40,000; to carry on a general milling business. Provisional directors: A. Dunlop, G. A. Dunlop and S. Rivers, all of Watford.

Weston Tool and Novelties, Limited; to manufacture and sell tools, cutlery, etc. Provisional directors: C. M. M. Colquhoun, H. E. Erwin, J. C. Webster, all of Toronto.

The Spanish River Navigation Co., Massey, Ont.; capital, $40,000; to build ships and vessels. Provisional directors: J. Errington, J. Sheets, J. S. Lowe, all of Massey, Ont.

Bain & Cubitt, Toronto; capital, $40,000; to manufacture paper boxes, envelopes and printers' machinery. Provisional directors: D. Bain, W. C. Cubitt, J. S. Denison, all of Toronto.

Imperial Rubber Co., Montreal; capital, $20,000; to make and deal in rubber and rubber goods. Incorporators: R. C. McMichael, D. J. Angus, R. O. McMurty, F. G. Bush, all of Montreal.

James L. Burton & Son Lumber Co., Barrie, Ont.; capital, $250,000; to cut and deal in lumber. Provisional directors: J. L. Burton, F. L. Burton, F. C. Lett, A. Alexander, W. H. Walter, all of Barrie.

O'Keefe-Sanford, Limited, Toronto; capital, $40,000; to manufacture and deal in mantels, tiles and fire place fittings. Provisional directors: W. Webb, M. Whelan, T. Main, B. F. Bennet, all of Toronto.

The Canadian Jack Co., Windsor, Ont.; capital, $25,000; to manufacture and sell a combination lifting jack and farmers' tool. Provisional directors: J. W. Yakey, M. Riddle, H. H. Calkins, all of Windsor.

Onaping Iron Ore Co., Toronto; capital, $200,000; to carry on in all its branches mining, milling and reducing of iron ores. Provisional directors: F. Denton, A. R. Cochrane, G. J. Valin, all of Toronto.

General Industries Construction Co., Toronto; capital, $100,000; to carry on a general construction business. Provisional directors: J. A. Patterson, G. F. McFarland, A. McKenzie, W. H. Templeton, all of Toronto.

Guelph Oil Clothing Co., Guelph; capital, $50,000; to manufacture and deal in oil clothing, tents, awnings, etc. Provisional directors: G. McPherson, J. T. McPherson, R. E. McPherson, G. A. McPherson, all of Guelph.

The Wiarton Steamboat Co., Wiarton, Ont.; capital, $20,000; to own and operate steamboats and carry on a wrecking business. Incorporators: S. Rutherford, T. C. Allan, J. A. Acres, W. H. Buchan, all of Wiarton.

The Dominion Wheel Co., Lindsay, Ont.; capital, $40,000; to manufacture and deal in all kinds of wheels and turned goods. Provisional directors: J. D. Flavelle, W. Mc. Flavelle, J. Carew, and T. Stewart, all of Lindsay.

The Cobbler-Sexton Co., Woodstock, Ont.; capital, $1,024,000; to carry on mining and milling reduction. Provisional directors: Wm. A. Hayward, J. C. Hovey, E. L. Greer, J. McClement, I. Draper, all of Woodstock.

The Bottle Exchange Company of Canada, Toronto; capital, $20,000; to manufacture and sell milk cans and dairy supplies. Incorporators: J. H. Lock, R. W. Dockeray, E. Grace, A. Anderson, V. E. Vansant, all of Toronto.

The Great Northern Petroleum & Asphaltum Co., Ottawa; capital, $100,000; to prospect for and deal in oil and asphaltum. Incorporators: J. G. Gibson, H. H. Williams, M. C. Edey, W. C. Perkins, R. M. Perkins, all of Ottawa.

The Crown Oil Refining Co., Hamilton, Ont.; capital, $40,000; to manufacture and deal in oil refining apparatus and refiners' supplies. Provisional directors: E. Hull, W. Perkins, J. A. Hull, T. Barnes, G. F. Hull, all of Hamilton.

The Tecumseh and Walkerville Oil and Gas Co., Walkerville, Ont.; capital, $40,000; to carry on an oil and gas business. Provisional directors: J. Dugal, P. Dugal, H. A. Walker, H. C. Walker, R. J. Colloton, all of Walkerville.

Victor Automatic Carriers, Montreal; capital, $20,000; to manufacture and deal in electric motors and dynamos and other power machinery. Incorporators: F. Filteau, F. H. Markey, R. C. Grant, G. G. Hyde, all of Montreal.

The Benson Lumber Truck Co., Port Arthur, Ont.; capital, $20,000; to manufacture and dispose of heavy farm and lumber machinery. Incorporators: A. W. Benson, N. O. Werner, E. L. Mattson, all of Minneapolis, Minn., and G. S. Clark and F. H. Keefer, both of Port Arthur.

The Interlocking Piling and Engineering Co., Limited, Toronto; capital, $200,000; to manufacture and deal in interlocking, piling and piling of all kinds, and carry on the business of engineers. Provisional directors; H. E. Pearce, A. Gate, W. H. Smith, G. Kerwin, M. Irving, all of Toronto.

The Natural Gas Supplies Co., Montreal; capital, $18,000; to carry on a plumbing and gas fitting business and deal in oil and gas wells. Incorporators: H. G. Eadie, H. P. Douglas, W. L. Bond, E. Chamberland, M. D. Barclay, all of Montreal.

E. and T. Fairbanks & Co., Sherbrooke, Que.; capital, $150,000; to manufacture and deal in scales, weighing instruments, and machinery of all kinds. Incorporators: H. N. Turner, J. C. Clark, P. F. Hazen, C. H. Turner, all of St. Johnsbury, Vermont, U.S.A.

William Hamilton Co., Peterborough, Ont.; capital, $300,000; to deal in machinery, contractors' and builders' supplies and carry on the business of machinists and engineers. Provisional directors: W. G. Ferguson, W. S. Davidson, G. L. Hay, R. M. Glover, J. D. Clarke, all of Peterborough.

The New Liskeard Clock Co., New Liskeard, Nip.; capital, $40,000; to manufacture clocks, novelties, dies, tools and sheet metal work and to carry on the business of machinists and engineers. Provisional directors: S. D. Briden, J. Armstrong, M. McLeod, D. McKelvie, J. Redpath, all of New Liskeard.

The Lachute Graphite Mining Co., Township of Wentworth, Que; capital, $20,000; to mine, prepare and deal in graphite, plumbago, and silver, clay bricks, marbles, and all kinds of artificial stone. Incorporators: A. Guilbault, Lachute; Z. A. Fournier, St. Andrews, Que.; J. R. Hyer, A. T. Woeltje, F. B. Kelly, all three of Waterdown, N.Y.

Building Notes.

A large armory is to be erected at Fernie, B.C.

The new court house for Vancouver will cost $400,000.

Tenders are invited for an armory for Brandon, Man.

A hotel will be erected at Kenora, Ont., to cost $225,000.

The Bank of Montreal will erect a block in Sudbury, Ont.

A new church will be erected at Lorette, Que., costing $100,000.

The new C.P.R. sample room at Vancouver will cost $28,000.

A fish hatchery will be erected at Newcastle, B.C., to cost $5,000.

A mission school will be erected at Kitamaat, B.C., to cost $25,000.

H. Robb, Winnipeg, will erect an apartment block, to cost $58,000.

J. Murphy will erect a business block in Fort William, to cost $15,000.

The new Seamen's Institute Building, at St. John, N.B., will cost $15,000.

A morgue and ambulance house will be erected in Toronto, to cost $30,000.

A police station will be erected in Toronto on Queen street, to cost $25,000.

D. Gibb & Son, Vancouver, will erect an apartment house, to cost $115,000.

The new medical building at McGill University, Montreal, will cost $500,000.

A building will be erected by the Y.M.C.A. in St. John, N.B., to cost $60,000.

Bushnell and Varty will erect an apartment block in Vancouver, to cost $20,000.

The new college building to be erected at Point Grey, B.C., will cost $100,000.

The Robert Crean Co., Toronto, will erect a warehouse in that city to cost $10,500.

A. E. Carter, Vancouver, will erect an apartment block in that city to cost $40,000.

A new wing is being erected at the Hotel Dieu hospital, Campbellton, N.B., to cost $40,000.

The contract for the building of the new court house at Victoria, B.C., has been award-

ed to McDonald, Wilson & Snyder, of that city. It will cost about $400,000.

The trustees of the University of Toronto will erect a residence in that city, at a cost of $150,000.

The grand stand at the Ottawa exhibition grounds was destroyed by fire, entailing a loss of $60,000.

Business Systems, Ltd., will erect a large building in Toronto for a commercial school, to cost $50,000.

The congregation of Annette street Methodist church, Toronto Junction, will build an edifice to cost $50,000.

The corner stone of the new high school at Picton, Ont., was laid recently. The building will cost $50,000.

The new edifice for the congregation of St. Andrew's Presbyterian church, Fort William, will cost $946,500.

The Edmonton Steam Laundry Co., Edmonton, Alta., are erecting an addition to their plant, to cost $2,000.

The contract for the new Bank of Commerce building, Brantford, has been let to Schultz Bros. It will cost $30,000.

The British Columbia Permanent Loan & Savings Co. will erect an office building in New Westminster, to cost $40,000.

Municipal Undertakings.

The new jail at Sydney, N.S., will cost $13,550.

Gracefield, Que., will install a waterworks system.

A court house will be erected at Saskatoon, Sask.

Massey, Ont., will spend $10,000 in waterworks.

Halifax, N.S., will install water meters, at a cost of $50,000.

Whitewater, Man., will install a municipal telephone system.

The village of Hintonburg, Ont., will raise $10,000 for waterworks.

A new pump house and equipment will be installed at Ottawa East.

A provincial jail will be erected at Moosemin, Sask., to cost $50,000.

The town of Sudbury, Ont., will ... 000 in waterworks extension.

New municipal buildings will be erected at Stirling, Alta., to cost $12,000.

Nelson, B.C., is considering the installation of a municipal telephone system.

A municipal waterworks system will be installed at South Vancouver, B.C.

The ratepayers of St. Felicien, Que., will vote on a by-law for a waterworks system.

A by-law has been passed at Welland, Ont., to raise $11,940 for waterworks extension.

A town hall and public library will be erected at Hanover, Ont., at a cost of $23,000.

The ratepayers of Wellington, Ont., will vote on a by-law for $1,000 fot sidewalk construction.

The ratepayers of Amherstburg, Ont., will spend $2,500 in improving the waterworks system.

Work on the hydro-electric power survey between Brantford and Hamilton has been commenced.

A by-law will be submitted to the ratepayers of Hamilton, Ont., to raise $500,000 for waterworks pumps.

A Worthington steam pump has been installed at the Point St. Charles station of the Montreal waterworks.

The Portage la Prairie council will ask for a grant for $50,000 for the completion of the waterworks system.

The Pelham, Ont., town council have given permission to two power companies to furnish electricity to that town.

The town of Ingersoll, Ont., will purchase the waterworks for $95,000, subject to the passing of the necessary by-law.

The corporation of Berlin, Ont., have received permission to acquire the interests of the Berlin & Waterloo Street Railway.

The ratepayers of Battleford, Sask., will vote on a by-law to raise $10,000 for a bonus to the Battleford Milling and Elevator Co.

The contract for the municipal lighting system for Battleford, Sask., has been awarded to J. Stewart & Co., Winnipeg, agents for the Canadian Westinghouse Co.

The official tests on the new eight hundred kilowatt plant at Morrisburg, Ont., were made recently by Mr. Willis Chipman, C.E., and Mr. K. L. Aitken, C.E., both of Toronto.

There is a by-law before the municipality of Alliston, Ont., to grant the Lloyd & Buchanan Mfg. Co. a free site and a loan grant of $500. A factory will be erected to cost $10,000.

The council of the town of Morden, Man., have awarded the contracts for the municipal electric lighting plant. The steam plant will be installed by the Robb Engineering Co., Amherst, N.S., and the electric portion by the Allis-Chambers-Bullock, Limited.

Railroad Construction.

The Canadian Northern will erect a bridge over the Assiniboia river at Winnipeg.

The C.P.R. have given $30,000 for a railroad Y.M.C.A. to be erected at Kenora, Ont.

The permit has been issued for the new C. N.R. shops at Winnipeg, to cost $200,000.

The C.P.R. will erect a coal handling plan at Fort William, Ont., to cost $1,250,000.

Track-laying will be commenced on the Mackenzie & Mann line at Garneau Junction, Que.

The Canadian Northern have been asked to build a line from Cobalt to Parry Sound, Ont.

The G.T.R. have commenced the construction of the line from Kitamaat to Kitsalas Canyon, B.C.

The Canadian Northern line from St. Jerome to Montford, Que., will be in operation this fall.

The C.P.R. will immediately take steps to double-track their line from Brandon to Winnipeg.

The new coal chute for the C.P.R. at Lethbridge is completed and giving complete satisfaction.

The Sydney and Glace Bay Railway, Sydney, N.S., will erect their central power station at Dominion No. 4.

The G.T.R. will spend $150,000 in enlarging and improving their shops and roundhouse at St. Thomas, Ont.

Saskatoon and Goose Lake, Man., have petitioned Mackenzie & Mann for a branch line between those towns.

The C.P.R. has let the contract for the line running northwest from Moose Jaw, by way of Lacombe and Edmonton.

The C.P.R. will erect new roundhouses at Coldridge and Strathcona, Alta.; Swift Current, Sask., and Cranbrook, B.C.

The contract for the stores building for the T. & N.O. railroad at North Bay has been let to O'Boyle Bros. Construction Co., North Bay.

The Canadian Northern have placed the contract for two switching locomotives with the American Locomotive Works Co., Philadelphia.

The farmers around Goose Lake, Sask., have given the Canadian Northern 52 miles of free right of way to run a line from Saskatoon to Wigins.

The Canadian Northern Railway and the municipal government of Saskatchewan will build jointly a bridge over the Saskatchewan river at Prince Albert.

The Temiskaming and Northern Ontario Railway commissioners recently decided to purchase ten new locomotives from the Canadian Locomotive Co., of Kingston.

The plans for the new Central Station for the G.T.R. at Ottawa have been approved, and work will be commenced immediately. The cost will be a million dollars.

The new bridge which the C.P.R. proposes to build at Lethbridge will be one of the most remarkable structures of its kind in the world. For two-thirds of its length the bridge will be over 300 feet high. There will be 22 spans 100 feet long, 44 sixty-seven feet long, and one 167 feet long. The steel used in its construction will weigh 10,000 tons, and will be supplied by the Canada Bridge Company, Walkerville, Ont.

Mining News.

The Silver Queen mine, Cobalt, Ont., will erect a smelter.

A large two-stand converting plant will be erected at the Boundary mines, B.C.

A valuable deposit of silver and lead has been discovered near Loon Lake, N.S.

There is a scheme on foot for the erection of a large smelter at Cobalt. Guggenheims are interested.

Spokane capitalists have formed a company to operate the Sure copper group, near Bella Coola, B.C. Machinery and supplies have been purchased and are being shipped.

A deal was completed recently by which a syndicate of Nelson men secured control of the Goodenough and Blue Bird properties at Sandon. A fund of $25,000 was subscribed, and development will begin immediately. J. A. Whittier will be in charge of the operations, and L. Pratt is treasurer.

J. B. Hall Moves.

J. B. Hall, machinist, Toronto, has moved from 110 Adelaide street W., to 115½ Simcoe street.

* * *

Canada Nut Co. Moved.

The Canada Nut Co. have moved from Toronto to Niagara Falls, their plant in that place being now completed.

* * *

Molding Shop Addition.

The Gilson Mfg. Co., Guelph, Ont., are putting up a molding shop, as an addition to their plant, which has but recently been completed. The shop will be 110x67 feet, and will be equipped with modern foundry equipment for molding gas engine cylinders and other engine parts.

* * *

Gasoline Motor Cars.

The Union Pacific Railway are placing in service on their lines twelve gasoline motor cars for last and frequent service. These cars, which are equipped each with a 200 h.p. engine, will make 60 miles an hour. They will reach high speed within six car lengths, and can be stopped within 120 feet.

* * *

Standard Fittings Plant Completed.

The plant of the Standard Fittings and Valve Co., Guelph, has now been completed, and manufacturing operations have been started. They at present are making cast iron fittings altogether, but later brass fittings and valves will be made. The management of the company say that the product of the plant will be sold to dealers only, and not direct to consumers.

* * *

Brantford Screw Co. Installing Gas Plant.

The Brantford Screw Co., Brantford, are installing a Pintsch producer gas plant as a reserve in case that natural gas gives out. At present their new plant is operated by gas engine running on natural gas. There is always the danger of this giving out, and the Economic Power, Light & Heat Supply Co., Toronto, are installing a producer gas plant as a reserve.

* * *

To Build Factory in Toronto.

A company to manufacture a new kind of incandescent electric light are thinking of establishing a plant in Toronto for the manufacture of the "Helion" light, which differs from the ordinary incandescent light in the composition of the filament. The lighting abilities of these lights will be demonstrated at the Toronto exhibition by W. W. Campbell, representative of the company who has an office in the Stair building, Toronto.

* * *

Further Addition to Hamilton Bridge Works.

A further addition is being made to the structural shop of the Hamilton Bridge Works, Hamilton. The new shop will be 72x180 feet, and building operations have been commenced. This new plant will be equipped with 90-foot span, 400-foot runways, electric traveling crane.

The building will be steel fireproof construction. All the machinery will be driven direct by electric motor.

* * *

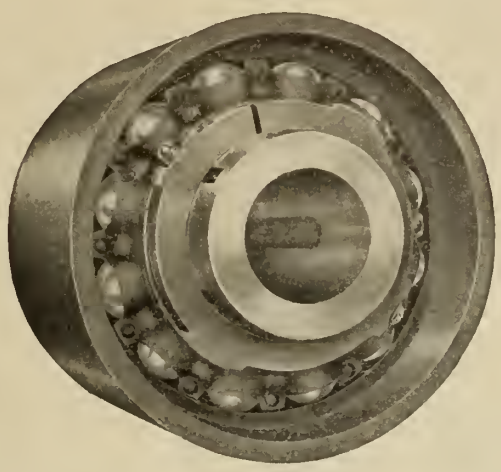
Gas Made From Straw.

A way in which to utilize the immense amount of straw which accumulates in the Northwest has apparently been discovered by Russell Coutts, Cleveland. Mr. Coutts is a graduate of Toronto University in chemistry, and while at Carman, Man., recently, he made a discovery which led him to investigate the possibility of producing gas from, otherwise, waste straw. This investigation was carried on at Oxford University and in New York, where he used an experimental gas plant loaned him for that purpose by the New York Gas Consolidated Co. In this plant he succeeded in obtaining 16,000 feet of gas from a ton of straw. At first, considerable trouble was had with carbon dioxide, but this was finally overcome by treatment with incandescent carbon and oil enrichment. The gas finally obtained equalled in richness the average run of coal gas.

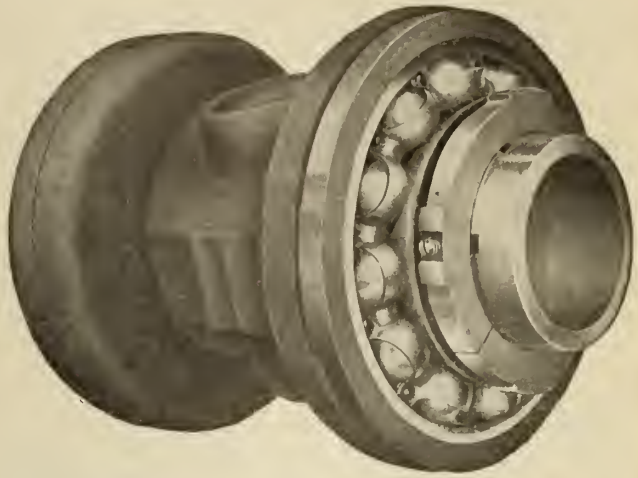
The patents of this process are held by the International Heating & Lighting Co., of Cleveland, and this company have in operation now a $100,000 plant in Beatrice, Neb.

Chapman Double Ball Bearings

Are Specially Adapted to be Used Wherever Friction Exists



Loose Pulley Bearing



Chapman Double Ball Bearing for Shafting

Transmission—	*Vehicles—*	*Trucks—*	*Cars—*	*Machines—*	*Special—*
Clutch Couplings	Automobiles	Express	Dumping Cars	Emery Grinders	Baby Carriages

The Chapman Double Ball Bearing Company of Canada

LIMITED

339 to 351 Sorauren Avenue — **Toronto, Canada**

At present it is proposed to build a plant at Brandon, Man., to cost $..... It is also proposed to erect similar plants at Edmonton and other western points.

* * *

Gas Plant Installation Decided Upon.

The long-talked of producer gas plant installation for the McClary Mfg. Co., London, Ont., has been quite decided upon. The installation will consist of a 200 h.p. suction producer gas plant and engine. The plant is being installed under the supervision of J. C. Royce, consulting engineer for the McClary Mfg. Co. The plant and engine are being built by the Weber Gas Engine Co., Kansas City; and the engine is of the vertical triple cylinder type, arranged to be direct connected to a Westinghouse generator.

The plant, when completed, will be tested thoroughly by the engineer in charge of installation; and the results of this test will be published later.

* * *

Steel Plant for British Columbia.

J. T. Shadforth, Ironmaster, Newcastle-on-Tyne, one of the organizers of the North Pacific Iron & Steel Corporation, is at present in Vancouver, B.C., arranging for the amalgamation of the coal and iron interests preparatory to the erection of a modern steel works. It will make steel of all grades, including steel rails and ship plate, with a big ship-building plant. The initial capital will be raised in British Columbia, and a greater amount in Manchester and London.

The company will be registered for fifteen million, of which two million will be initial expenditure on plant, with a site near Vancouver. All the raw material is now found in British Columbia. The value and extent of the iron ores of the coast is only lately being fully realized.

* * *

Electrical Equipment of Quebec Bridge.

The bridge which is being built at Quebec for the Quebec Bridge and Railway Co. is arousing considerable interest, it being the longest single span bridge in the world. All the erecting work is being done by electric motor. Alternating current is supplied from the Chaudiere Falls at 2,400 volts, to two motor-generator sets made by the Allis-Chalmers-Bullock, Ltd., Montreal. These are situated in a sub-station on the approach span, and they deliver a 550 volt direct current to the motors on the traveler and elsewhere.

This being the first time that electric power has been used on structural steel erection work of any magnitude, the outcome of the experiment has been watched with interest, and the fact that no delays or break-downs have yet been experienced speaks well for electric power for this use, and for this installation in particular.

* * *

Transformer Building Complete.

The large new transformer building for the Canadian General Electric Co., Peterboro', Ont., has been handed over by the contractors, the Dominion Engineering and Construction Co. The structure is entirely fireproof, being of concrete and steel. It is 80 feet broad, 52 feet high and 305 feet long. Along the east side of the building there is a large gallery, on which are located the machinery for winding the coils of the transformers. There is an electric crane, which travels the length of the building and has a capacity of 50 tons. There is a smaller crane of ten tons capacity. The oil for cooling the transformers is forced through pipes by an electric pump from a tank 500 feet from the building. The steel was supplied by the Canada Foundry Co., and the measurements were so accurate and the filling of the contract so faithfully done that practically no cutting was done on the ground.

* * *

Power From the Mine.

One of the greatest departures in solving the ever-present problem of obtaining cheap power was recently inaugurated in Nova Scotia. The plan is to develop power at the mouth of the coal mine and thus eliminate the necessity of transporting coal.

The Maritime Coal, Railway and Power Co., Amherst, N.S., acted upon a suggestion of Thos. A. Edison's, made recently in England, to build a power house at the mouth of their mine at Chignecto mines, N.S. Here they have installed a modern steam plant and propose to transmit the energy developed to several manufacturing centres.

The power plant consists principally of a Robb-Armstrong cross-compound, vertically-enclosed engine, developing 750 horse-power, under most economic conditions, but capable of carrying 1,000 horse-power on an overload. It was manufactured by the Robb Engineering Co., Amherst, N.S. The steam is supplied by four 200 horse-power, return tubular boilers, built also by the Robb Engineering Co. They are fed automatically by Jones underfeed stokers, and are arranged with induced draught.

Directly connected to the engine is a Canadian Westinghouse alternating current generator with a rated capacity of 500 kilowatts, delivering current at eleven thousand volts. It was manufactured by the Canadian Westinghouse Co., Hamilton, Ont.

The power will be transmitted at first to Amherst, a distance of 6½ miles, at a pressure of 11,000 volts. Here it enters a sub-station and is transformed down to 2,000 volts. At the sub-station are three Westinghouse transformers of 150 kilowatts each. There are three transformers of 40 kilowatts each, which reduce the pressure in some cases to 220 volts.

It is hoped that the cheap power generated at this station will be the means of bringing many industries to Amherst and vicinity.

A fully illustrated description will be given next month.

* * *

Addition to Armstrong Tool Plant.

Owing to the rapid increase of its business Armstrong Bros. Tool Co., of Chicago, have been compelled to make further additions to the large, modern plant which it erected about two years ago. These consist of two buildings of steel and brick constructions, one 50 feet by 105 feet, the other 90 feet by 105 feet, with brick smokestack 60 in. diameter, 115 feet high. In these buildings the company is now installing a modern power plant of 300 h.p., consisting of two 150 h.p. water tube boilers equipped with automatic stokers, direct connected engine and generator, etc., and an up-to-date drop forge department of large capacity with steam drop hammers of the latest improved design, and other high-grade equipment, including a complete die shop, with machine tools especially adapted to that important work.

The machinery is now being set in position and will be in operation about October 1st.

* * *

A New Machine Tool Company.

It is gratifying to watch the rapid development of the machinery business in Canada; and among the latest additions in this line is the Rawden Machine & Tool Co., Toronto. This company started out in a small way some months ago, but have now the beginnings of a fine machine shop. It is the idea of this company to build up a name for themselves on some standard line, and with this object in view, the company has started to manufacture a standard upright drill. The best of workmanship is being put on these tools, and a fine finish. The company expect this tool to give them their reputation.

Job work is done to fill in with.

There is plenty of room in Canada and a good future for a firm of this kind, and prosperity will surely be theirs if the business is built up along correct lines, chief of which is fine and accurate workmanship.

* * *

Canadian Cement Production.

The manufacture of cement in Canada dates from the year 1891, when operations were begun in a very small way at Marlbank and Shallow Lake, both in the Province of Ontario. The first year's output was 2,053 bbls., which is only a little more than the daily production of one of the modern plants. In 1892 the output was 20,247 bbls., and 31,924 bbls. in 1893.

The next ten years in the cement industry of Canada witnessed an increase of 50 per cent. each year over the production of the preceding year. Four plants were in operation in 1901, and now there are nineteen.

In 1906 there were fifteen plants in operation, with a total daily capacity of about 10,500 bbls., and according to the published figures of the Canadian Geological Survey, during the year 2,152,562 bbls. of Canadian cement were made, which represents an increase of 610,994 bbls., or 39.6 per cent. over the production of 1906.

Very little cement is exported from Canada. The consumption is due to the use each year of better and more improved machinery and equipment. An excellent example of a cement plant whose equipment will, when completely installed, be among the best in Canada, is that of the Western Canada Cement and Coal Company, which, some time ago, purchased through Allis-Chalmers-Bullock, Ltd., of Montreal, three Allis-Chalmers 1000 k.w. steam turbine generator units for use on the company's properties, located fifty-seven miles west of Calgary, Canada, on the Canadian Pacific Railway.

The units, which are now being erected, will generate current of 60 cycles, 3 phase, at 600 volts, and the coal to be used in their operation will be taken from the bankhead mines of the Canadian Pacific Railway and delivered at the mills.

The adoption of electrical drive for the operation of these cement mills, whose current will be derived from a steam turbine power plant, which will rank among the foremost installed for industrial purposes, is a frank acknowledgement of the well recognized superiority of electrical drive over mechanical forms in the cement-making industry.

The current generated from the turbo-unit will be devoted entirely to power purposes; the lighting load, consisting of some forty arc and four hundred incandescent lamps, will be carried by the exciters, also of Allis-Chalmers build, in addition to their work of exciting the turbo-alternators.

The equipment, built by Allis-Chalmers Company, for the Western Canada Cement and Coal Company, is not confined, however, to the two turbines described. Allis-Chalmers' cement-making machinery, comprising a 7½ style "K" and No. 4 style "K" Gates breaker, and sixteen tube mills are also in use there.

BOOK REVIEWS.

CAMBRIA STEEL.—The eighth edition of this handbook, published by the Cambria Steel Co., Philadelphia, Pa.

This edition contains most of the matter of the prior edition, with such corrections and revisions as have been found necessary to bring it up to date. The tables of sheared and edged plates have been revised and amplified to show the larger range of sizes which the company are now prepared to furnish, particularly in edged in universal plates. Several new sections have been added, and some revisions made in the tables of rounds, nats, billets, blooms and slates.

The table of "Properties and Principal Dimensions of T-Rails" has been revised, so that it now covers a full range of the American Society of Civil Engineers' standard sections.

ON THE ART OF CUTTING METALS.—The address made at the opening of the annual meeting of the American Society of Mechanical Engineers in New York, December, 1906, by F. W. Taylor, published in book form by the society; illustrated, with tables and diagrams; price, $5.

This address has created an immense stir in the mechanical world, and mechanical papers the world over have published more or less complete extracts from it. This is a book which every person interested in the cutting of metals should have, it being the most complete work ever published of experiments along this line.

BALANCING OF ENGINES.—An elementary text book, using principally graphic methods for the use of students, draftsmen and designers on this subject of balancing of steam, gas and other engines; by Archibald Sharp; 212 pages, 9x6 ins.; published by Longmans, Green & Co., 39 Paternoster Row, London, Eng.; price, 6s.

This book is very complete in itself, starting with simple mechanics and leading up to the higher forms of mathematics necessary for the solution of problems of this kind. The subject itself has for the most part been treated graphically. Many useful tables are contained in the back.

TESTS ON REINFORCED CONCRETE BEAMS.—Bulletin No. 148 of the University of Wisconsin contains a report of tests on reinforced concrete beams made by E. A. Moritz, C.E., instructor in mathematics; published by the University of Wisconsin, Madison, Wis.; price, 30 cents.

The report contains a general description of conditions of tests, and a detailed account of the results, including tables and curves, etc.

RAILROAD MEN'S CATECHISM.—An instruction book for enginemen, trainmen, signalmen and every person having to do with the moving of trains; by Angus Sinclair; 200 pages, 4½x6½ ins.; published by Angus Sinclair, Pub. Co., New York.

The questions used in this book are a series for the examination of engineers and firemen by a certain railroad system. Twenty questions for engineers and firemen have been added, the questions and answers being based on the standard code of the American Railway Association.

BUSINESS CHANCES.

WANTED—A large and well-equipped factory to build meat slicers; large quantities desired. Write for particulars to Wolf, Sayer & Heller, Montreal. [8]

A GOOD cash paying electric wiring business; a small capital only required; selling out owing to ill health. For particulars apply to Box 31, CANADIAN MACHINERY, Toronto. [8]

MANUFACTURERS AND MANUFACTURERS' AGENTS.

It will pay you to watch our condensed column each month. There are many money-making propositions brought to your attention here. You may find just what you are looking for.

RATES

One insertion—25c. for 20 words; 1c. a word for each additional word.

Yearly rate—$2.50 for twenty words or less, 10c a word for each additional word.

The above does not apply to notices under the head of "Machinery Wanted." These notices are inserted free for subscribers.

FOR SALE.

BELTING, RUBBER, CANVAS AND LEATHER, Hose, Packing, Blackamith's and Mill Supplies at lowest prices. N. Smith, 138 York Street, Toronto. (2tf)

AUTOMATIC stocker, with fan and engine complete, in good running order; snap; reason for selling, compelled to burn shavings. Apply A. J. H. Eckardt, National Casket Co., 107 Niagara St., Toronto. (9)

GASOLINE engine, 12 h.p., good as new; price, $275. Krug & Crosley, Hamilton. (9)

FOR SALE—The Canadian patent rights on a valveless pneumatic hammer, proved by actual test to be superior to any hammer at present on the market; an arrangement can be made to manufacture same on royalty for Canadian market. Apply Box 39C, CANADIAN MACHINERY, Toronto. (9)

MANUFACTURERS' AGENTS WANTED.

SHEFFIELD manufacturers of tool steel, spring steel, section bars, etc., as advertised on page 16, wish to correspond with reliable Canadian firms with view to sole agencies in certain territories. Address "Newhall," care CANADIAN MACHINERY, 88 Fleet Street, London, Eng.

SITUATION VACANT.

WANTED—Young man well experienced in machinery supply business able to sell and knowing thoroughly all requirements of the trade. Salary, commission and share of profits. Apply Box 32, CANADIAN MACHINERY, Toronto.

WANTED AT ONCE—Superintendent and mechanical engineer for machine works manufacturing gasoline engines and general machine work; one familar with modern methods, capable of making estimates, drawings and producing work at minimum cost; give full particulars of qualifications, experience, age, nationality and salary. Apply to Brandon Machine Works Co., Ltd., Brandon, Man. [9]

SITUATIONS WANTED.

ADVERTISER, shortly emigrating, seeks position as correspondence clerk and accountant. Well up in tail details of engineering and allied business; ledger balancing, shorthand and typewriting; excellent references. Lister, Ipswich Road, Ardleigh, Colchester, Eng.

A Firm of Chemical Engineers

are requiring first-class agents in the large cities of Canada. Apply to W. J. Fraser & Co., Ltd., Chemical Engineers, 98 Commercial Road East, London, England. [11]

We should have your business.

If prompt delivery, reasonable prices and best of workmanship appeal to you, we should have your pattern orders.

SEND FOR PATTERN CLASSIFICATION CARD

THE HAMILTON PATTERN WORKS

134 Bay St. N., HAMILTON, ONT.

Phone, 2664.

A Labor Saving Combination

Couch and forming rolls with special attachments for economical manufacture of pipes, complete machines made to meet your requirements (patent 94746), estimates furnished upon application.

Stuart B. Playfair

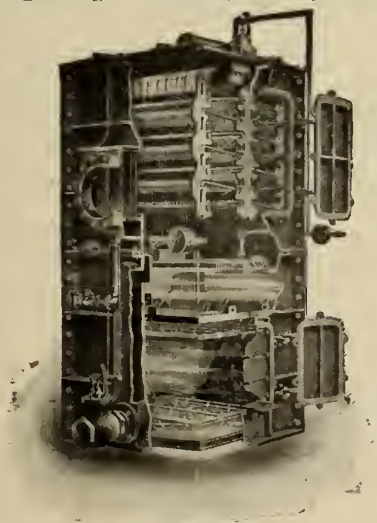
Traders Bank Building

TORONTO, - CANADA

An intelligent Engineer uses nothing but the GENUINE PENBERTHY INJECTOR. He has had experience with just-as-good kind before.

Commercial Sense!

It's simply a matter of sound business sense when it comes to saving money. We have made some pretty strong statements regarding the efficiency, economy and durability of Webster Heaters and we are ready to mail the proofs of our assertions to any manufacturer anywhere.



THE WEBSTER

FEED-WATER HEATER PURIFIER AND FILTER

is certainly a money-saver. The fact that there are fully 2,000,000 h.p. of Webster Heaters in actual use and all giving thorough satisfaction, proves our statement.

The general efficiency and unquestionable economy of the type shown in the cut is admitted by our competitors. It cannot waste steam, and does save fuel. Write for particulars.

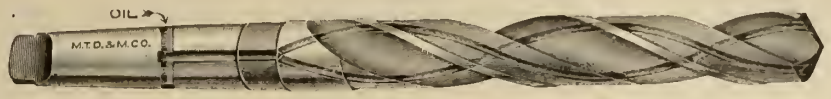
DRILLS WITH LUBRICATING HOLES



If you want to make a hole at a maximum of speed, and at the same time with the greatest accuracy, use one of our drills with holes from shank to point for conveying oil or other lubricant to the point of the drill. The general advantages of this form of lubricated drill over the ordinary twist drill are the greatly increased speed possible in drilling, the assistance given by the lubricant in the discharge of the chips, its durability and high cutting efficiency. The sizes commonly used are from ⅜ inch to 2½ inches diameter. Our drills have the lubricating hole through the solid metal; this latest improvement in lubricating drills being made solely by us under patents which we own. The special advantage of this drill over the other makes of drills with lubricating holes is that it is composed of one solid piece of steel; there is no part to work loose or wear out, the whole of the drill having the same life. In manufacturing large quantities of a single article having a drilled hole, one of our drills is invaluable. This is because of its long life, the speed at which it can be run without getting too hot for use, and the time saved by not having to withdraw the drill from the hole to cool it or to remove the chips.

Electrical Power Plants a Specialty

Alternating Current Motor

SUPPLIERS OF:

Hydraulic and Pumping Plants
Electrical Generators
Electrical Motors
Arc Lamps, ordinary or flame
Cables, high and low tension
(Specialty in Paper Insulation)
Switchboards
High-Tension Switch Gear
Supply Meters
Transformers
High-Efficiency Incandescent Lamps
Gas Engines and Producer Plants

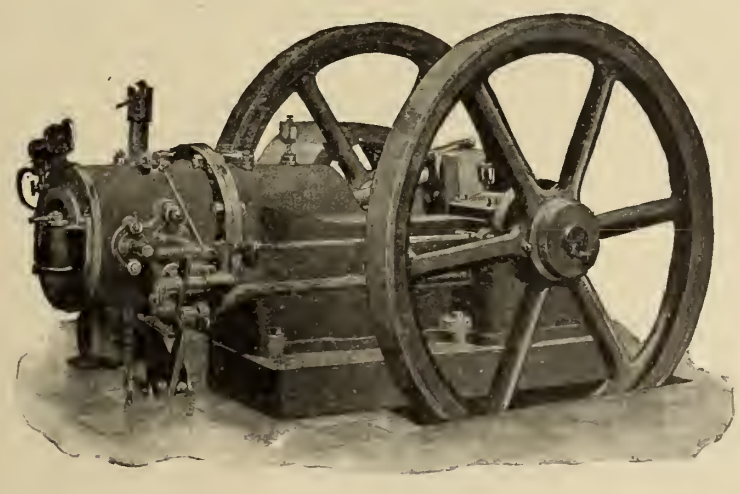
Direct Current Motor

SEND US YOUR ENQUIRIES, NOTHING TOO LARGE OR TOO SMALL

GAS AND ELECTRIC POWER COMPANY

Stair Building
Bay Street
Toronto

NO ASHES TO BURN



IF YOU USE A

"PREMIER" GAS ENGINE

and when installed with a **Canada Gas Producer** it will save more coal than burning ashes.

LET US TELL YOU ABOUT IT.

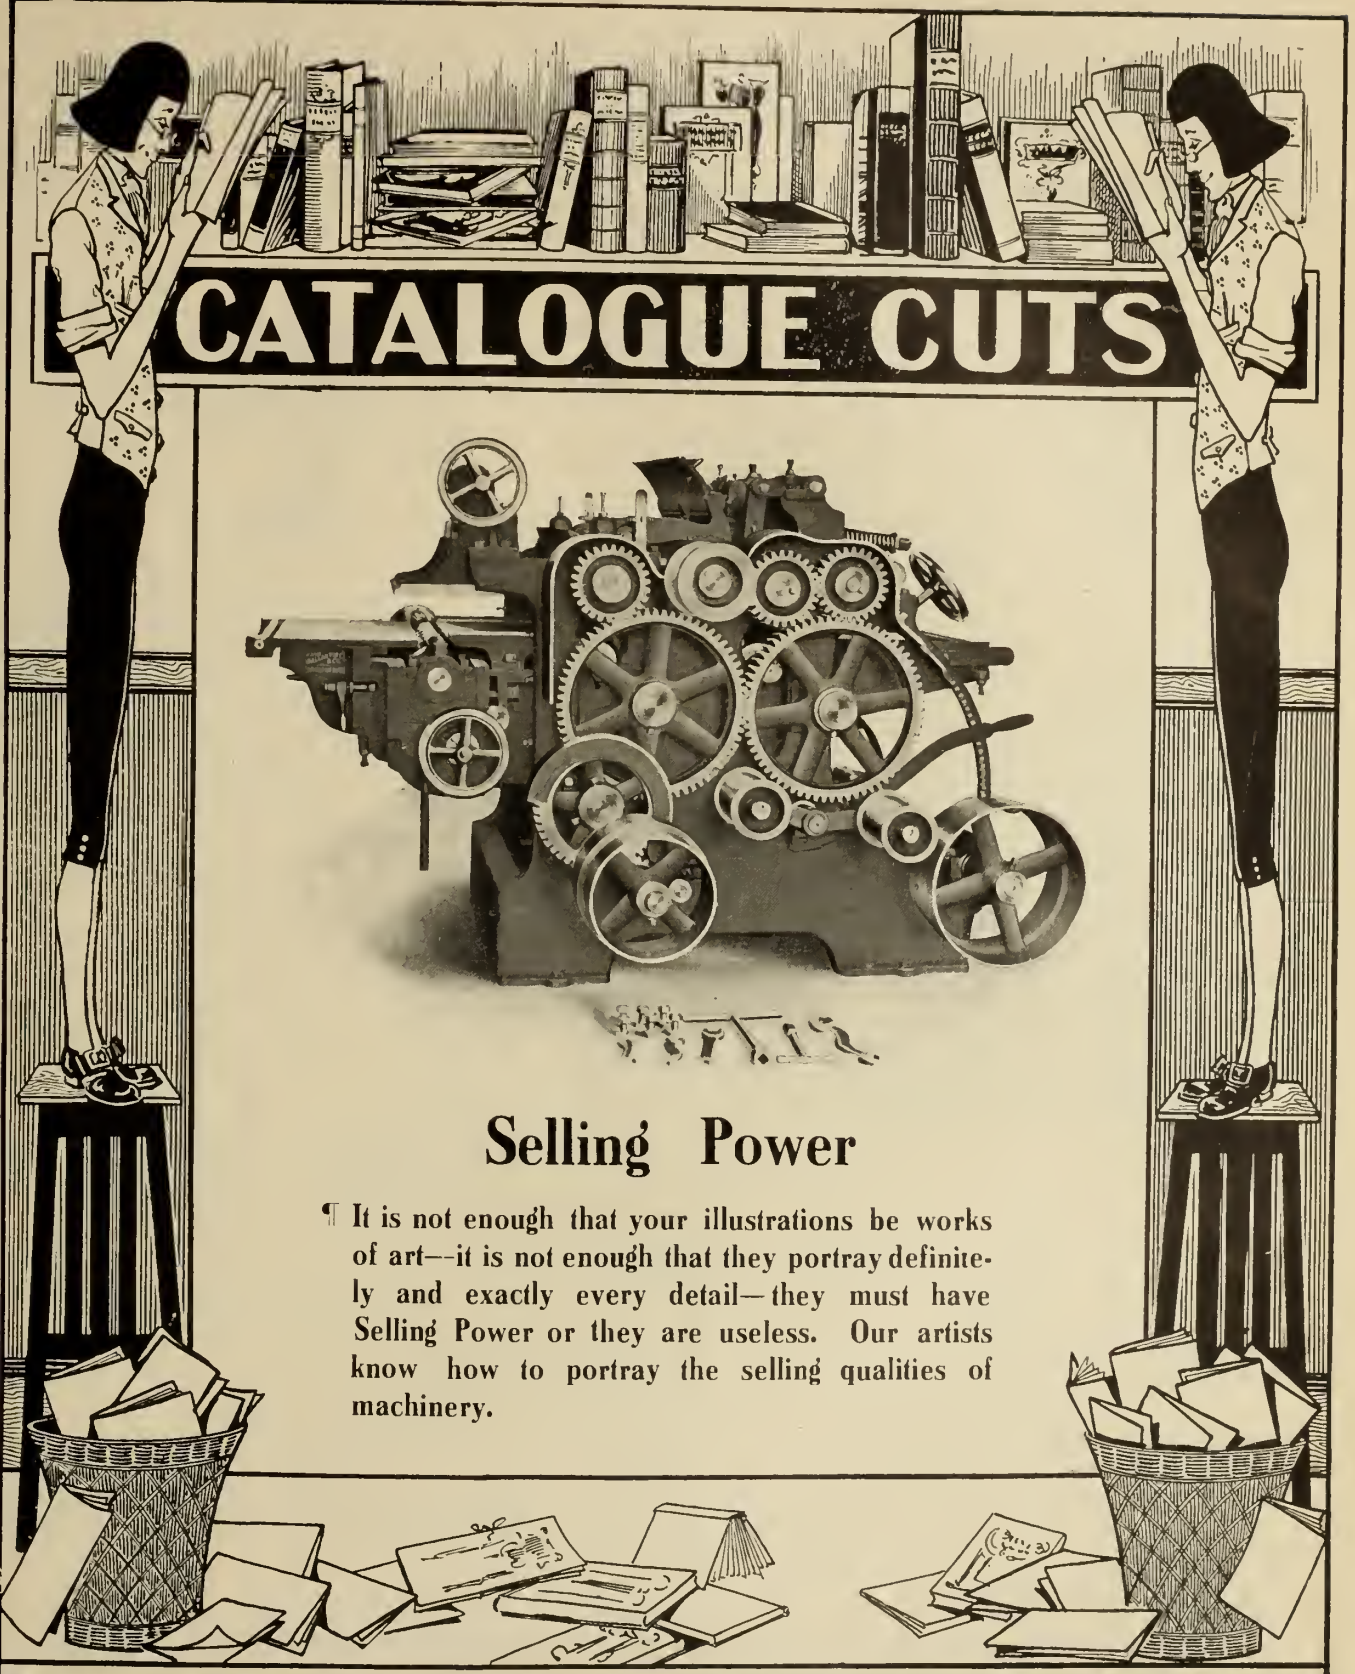
Canadian Machinery and Manufacturing News

is a medium through which you can talk to 95 per cent. of the citizens of Canada who must be consulted when Machinery, Tools, Power Equipment and Industrial Supplies are to be bought. If your announcement does not appear regularly you are missing opportunities for increased business.

Let us Send you Rates and Further Particulars



Selling Power

¶ It is not enough that your illustrations be works of art—it is not enough that they portray definitely and exactly every detail—they must have Selling Power or they are useless. Our artists know how to portray the selling qualities of machinery.

THE TORONTO ENGRAVING CO. LIMITED

92-94 BAY ST, TORONTO.

MALLEABLE IRON CASTINGS

WE ALSO MAKE METAL PATTERNS

Galt Malleable Iron Co., Limited - Galt, Ontario

Partine

THE UNIVERSAL PARTING.

Trade Mark Reg. U. S. Patent Off.

Preferred by Leading Foundrymen to Lycopodium

Partine does not run, cut, wash or burn off the face of the mould.

Guaranteed to produce, in every instance, a PATTERN TRUE casting, displaying the most delicate lines and features of an artistic design, accompanied by an absolute smoothness of the edges of the metal.

Its price is so low as to make its use imperative in every modern foundry.

Write for free sample, descriptive booklet and full particulars.

Sole Canadian Agents: THE HAMILTON FACING MILL COMPANY, Limited

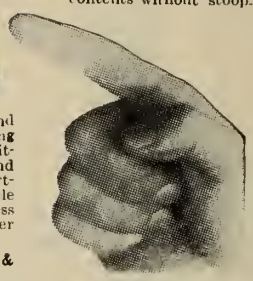
Cable Address: PARTINE

THE FOUNDRY SPECIALTY CO., Cincinnati, O., U.S.A.

THIS TUMBLER HAS BUT ONE LEG

to stand on—a mighty good feature in itself. It has so many points of superiority that we won't attempt to enumerate all. Admits of perfect action on the barrel's contents without stooping. No spilling and picking up requiring time. Occupies very little floor space. Send for "The Silent Partner," that famous little magazine of cleverness and our new Tumbler Book. Address



THE GLOBE MACHINE & STAMPING CO.,
899 Hamilton St., Cleveland, O.

Persons addressing advertisers will kindly mention having seen advertisement in this paper.

"PARTAMOL"

The Acknowledged Standard Parting for Parting Molds

The Money Saver and Profit Producer

"Success means willingness to put aside the old for something better."

Partamol is the something "best" in parting compounds. It turns out a perfect mold with every line true to pattern. Allows of easy and perfect "slicking" of the mold. The results from its use will astonish you. The price will please you. Sample on request.

TOOL ROOM ECONOMY:—

The Use of Diamo-Carbo Emery Wheel Dressers.

The ***Diamo-Carbo Dresser*** is the only satisfactory substitute for the black diamomd. Permits you to true and shape your wheels just the same as with the more expensive device. and s adapted for use on all tool grinding wheels. The hardest abrasive known; wears indefinitely; and cannot get lost or broken and will not injure the edges of the most delicate wheels.

Made in three lengths: 8", 10" and 12" respectively.

Prices: $3.00, $3.50 and $4.00

Tell us which length is best suited for your needs, and let us send a Dresser on ten days' trial. Booklet and testimonials for the asking.

DO YOU USE **PLUMBAGO** IN YOUR FOUNDRY?

If you do, we would like to submit a sample of our

Columbia Dry Sand and Loam Facing

which we are now marketing, and which will cost you from 200 to 300 per cent less than your Plumbago, yet gives as good, if not better, results.

It can be used on the heaviest kinds of cores, dry sand, loam and skin dry work. The sample will cost you nothing, as we know that a trial will convince you of its economy and plainly show its many advantages; therefore we will be willing to stand this expense, if you will give it a fair test.

WE CONTEND THAT

The Busy Man's Magazine

IS the best publication in the magazine line. But don't take our word for it. Read the unsolicited opinions of its subscribers—

"I consider The Busy Man's Magazine the best I have yet come in contact with." Henry Wilson, Toronto.

"It is the most interesting publication of its kind I have ever subscribed to." G. F. Haworth, Toronto.

"There is no better printed in the world to-day for busy men." B. T. Petch, Regina, Sask.

"Your magazine is the best I have ever had the privilege of perusing." S. W. Wynn, Yorkton.

"We would not like to miss the future copies of The Busy Man's Magazine." Ingersoll Packing Co., Ingersoll.

"I am pleased to say that each number is becoming more valuable and interesting." A. B. Musselman, Berlin.

"I am more than pleased with my investment in The Busy Man's Magazine, believing it to be the best magazine I have had the pleasure of perusing." A. B. Burrell, Amigari.

"I have been delighted with the Busy Man's Magazine. The articles are well chosen, are concise and ably written. For a busy man I know of no other magazine that will compare with it." Geo. Anderson, Toronto.

"The articles in The Busy Man's Magazine are just what we want, short and so well written that a busy man can afford time to read them and feel benefited for the short time given to each article." Wm Thoburn, Almonte.

We wish to give you further proof of the value of the ***BUSY MAN'S.*** Send us a postcard, giving your address and we will send you a sample copy.

Bear in mind every timely, interesting and instructive article appearing in any of the current magazines and periodicals appears also in the ***BUSY MAN'S***—a hundred magazines for the price of one.

STARRETT TOOLS

ARE THE STANDARD

FOR ACCURACY, WORKMANSHIP, DESIGN AND FINISH

STEEL TAPES

IN STEEL OR LEATHER CASES

In our tapes the figures denoting feet are smaller than those denoting inches. Two reasons for this:

This dissimilarity of figures materially lessens (in fact ought to entirely prohibit) the liability to erroneous readings that frequently occur through the uniformity of all figures in steel tapes of other makers.

The smaller figures, denoting feet, allow the graduation line under each to be plainly visible, instead of being obliterated by the usually larger figure.

Graduated in feet, inches and eighths of an inch, or in feet, tenths and hundredths of a foot.

CHICAGO, U.S.A.

THE HYPER-ACME
Chain Pulley Block

The friction in this block is automatically cut off as the load rises, and consequently only the load being raised need be reckoned on, thereby reducing the power required by more than one half.

The ordinary screw block has only the single worm and that of a very fine pitch, thus making the process of raising very slow, whereas in the "Hyper-Acme" pulley block the room is of very coarse pitch, causing the load to rise with great speed. The lowering of light or heavy weights is done with ease and rapidity. Sizes from ½ to 10 tons carried in stock.

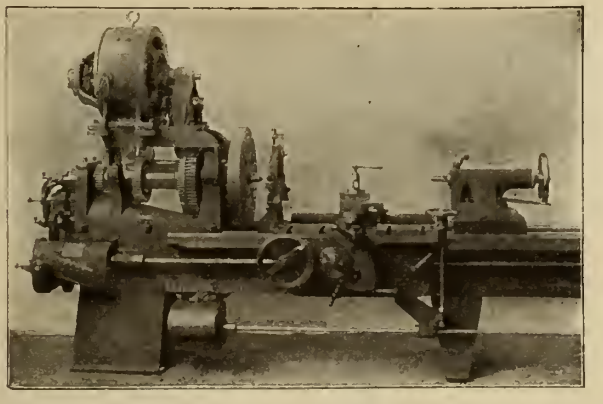
Westinghouse Motor-Drive

For Machine Tools.



Westinghouse Motor Driving Johnson, Jr., Co.'s Lathe.

Electric drive allows of great flexibility in arrangement of tools and in making additions to the plant. On account of its easy regulation and control, it always keeps the tool at its maximum capacity, and thus makes both tool and operator more valuable. Reliable data shows an increase of more than 25 per cent. in the producing capacity of electrically driven shops, as compared with mechanical drive.

Radial Simplicity---

A Matter of Importance!

1 —You know pretty well what a good Radial ought to be. It should have a large number of speed changes—to adapt it to metals of all degrees of hardness—a wide range of feeds, from one of sufficient fineness for drilling small holes in steel, to one of suitable coarseness for boring large holes in cast iron ; a multiple automatic trip, a zero dial depth gauge, and such other features as would enable it to produce a maximum in output.

2.—But these features, necessary as they seem to be, are of little practical value unless they are of simple design and easily accessible.

3.—There's little gain, if any, in having a wide range of speeds or great variety of feeds, if the operator is put to the necessity (meaning delay) of shifting his position every time a lever is to be manipulated. Nor can you afford to have him waste time trying to fix a complicated machine.

4.—Your cost records are your drilling records, from which it would appear that the machine of greatest productive capacity would be one of such features as are simple in construction and of extreme convenience to the operator.

5 —Bickford Radials are rigid, durable and accurate. They embody such cost-cutting and labor-saving devices as enable them to produce a maximum in output, and their design is of the simplest. It is next to impossible for them to get out of order, and they handle so conveniently that even a boy without experience can run them and get good results.

6.—For an honest and detailed description of these drills send for our catalog. It tells all about them and contains valuable "Radial" pointers for the man who is interested. A postal with your name and address is all that's necessary.

That's expensive. Better sharpen the cutters. You can do this very quickly on

The Cincinnati Universal Cutter and Tool Grinder

It will sharpen anything in the cutter and reamer line, and will grind up new cutters all over.

We can furnish an attachment for sharpening 12-inch face mills and end mills with large shanks.

It does the work quicker and better than any Grinder made. Any boy can operate it and get good results.

Don't waste money using dull cutters simply to save the price of a grinder. You'll have to get one some time. Why not now?

Ask for Treatise showing forty examples of Cutter and Tool grinding

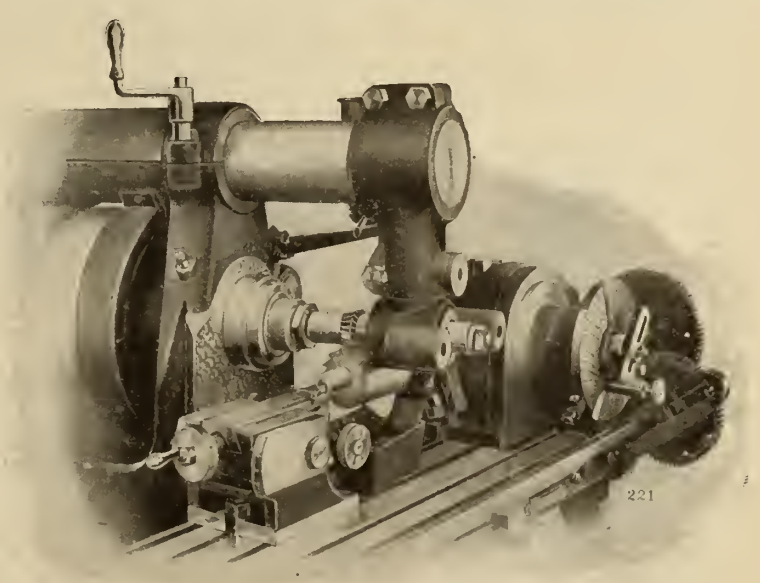
TORONTO - - MONTREAL

Toolroom Millers



We make all sizes, from small No. 1 up to the No. 4, which is the most powerful Universal made by anyone.

We are Milling Specialists

The No. 2 Universal Cincinnati Miller

does work like this: It is making a 3 in. diameter spiral mill out of a Novo steel blank, cutting teeth .275 in. deep by ¾ in. wide at the top, at a single cut, running 56 r. p. m.—feed per turn .033 in.—which gives a table travel of nearly 1⅞ in. per minute.

This is a modern practice on this popular toolroom machine, and is possible because it is convenient to operate. We guarantee its accuracy to be unexcelled. It is in all respects a precision tool. Let us figure on your toolroom requirements.

CARBORUNDUM
NIAGARA FALLS

LET our experts prescribe for your grinding needs.

Grinding is a scientific operation these days.

Manufacturers rightly demand, not merely a grinding wheel, but the most economical grinding wheel that can be produced.

And the Carborundum Company's trained experts are here to supply the demand.

There are something like 200,000 different sizes and grits and styles of wheel regularly made, and a lot more that are made to order for special purposes—

And each individual wheel does some one thing better than any other wheel.

If you will wrtie us your grinding needs we will be glad to tell you the wheel best suited to your particular requirements.

Let us send you the Carborundum book.

The Carborundum Company
Niagara Falls, N.Y.

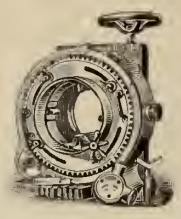
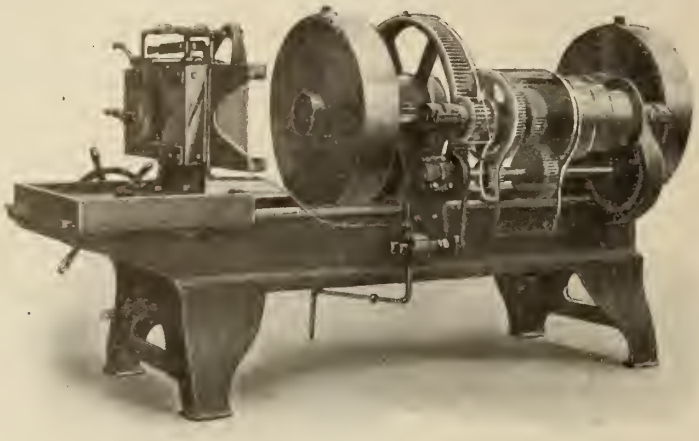
THE CURTIS & CURTIS CO., - *36 Garden Street, Bridgeport, Conn.*





THIS IS THE NEW SHANTZ No. 6.

BAD THREADS—LOST MONEY

That, in brief, is the tale which could be told by many a man who still sticks to his old-fashioned pipe-threading machine. It is surely the worst form of **extravagance** to keep an **obsolete, money-wasting** machine in the shop, especially when, at a reasonable price, the

SHANTZ No. 6

fitted with the **Borden Patent Solid Adjustable Die Head,** may be installed. This machine **cuts absolutely perfect threads** on 1½-inch to 6-inch pipe. It does the work **with one cut,** and does it quicker and cleaner than any other machine in America. **Absolute accuracy** can be obtained by the mere adjustment of an adjusting screw. This machine weighs 4,300 pounds, and is **so immovably rigid** that **a wavy thread is an impossibility.** And there are other points about it, which, with those above stated, place the **"Shantz No. 6"** in a class by itself. **Write for our free descriptive circular.**

I. E. SHANTZ & CO., Berlin, Ont.

Elements of Crane Construction

By C. C. MAISON

In no structures built by engineers is the question of due relation of strength to stress of greater importance than in cranes. Yet in few does more empiricism exist, in few is the accumulated experience of success and failure of greater value—a case which has notable parallels in the history of the development of the locomotive crane, and of machine tools, neither of which are much indebted to theory. There are certain crane elements in regard to the strength of which calculations are of much value, because the stresses are readily obtainable by the methods of graphic statics. These are the elements of which the cranes are built, and the strains on chains, hooks and snatch blocks. But the main side frame castings, and the plated frame castings, are not readily calculated, and, in fact, are almost invariably copied or modified from previous designs that have stood

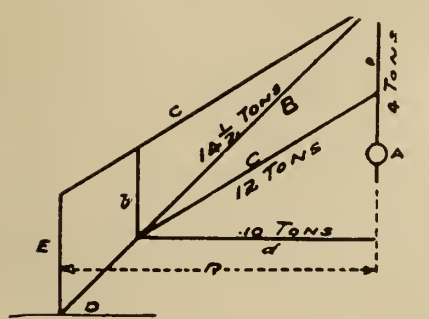

FIG. 1.
Raking Jib Type.

successful service. In the drawing room of crane shops new designs are got out without much direct calculation, because previous practice is drawn upon. The more highly the work of a firm is specialized, the more easily can modified designs be produced. There are tables kept in the office, giving loads for various sizes of chains, wire rope, and the strength of the different standard hooks used, the strength of rods of various cross sections, and a deal more of the same character, by which direct, often repeated calculations are rendered unnecessary. Then there are certain points of gears and drums which have been previously used, and these can be taken en bloc, and put on other cranes that vary in details of design. Jibs are standardized for different radii and power, and these need not be re-calculated. So are trucks, posts, ground wheels, and then, too, there are standard superstructures that can be taken bodily and put on either portable or fixed bases. The reason why calculations are so greatly modified is that stresses can be obtained for certain elements with absolute precision, and in others with a fair approximation thereto.

In the writer's experience, there is no single section of a crane which has not been overworked, whether checks, posts, jibs, chains, the rods, trucks, both cast and plated, traveler girders, tooth wheels and drums. Accidents occur because the machine is called upon to perform work which it was not designed to do, and very often the cause is the reliance placed in past actions, which a certain crane did over or nearly half a century ago. There are few machines, speaking indiscriminately, that are more ill used than these.

The checks of cranes are subject to great variations in design. In small cranes they are of cast iron; in heavy ones, steel plated. But many small cranes are cheaply made with steel plate, while for permanent way cranes this type is always employed. Plated work is to-day thirty per cent. cheaper than formerly, and is by far more reliable than castings. But castings cost still less, because the bearings are in one with the frame, while in plated work the bearings must be prepared separately and bolted or riveted on. But these are often cheaply fitted in the form of round bosses in place of the more expensive divided bearings, according to the purchaser, of course.

In the simplest types of the true cranes the elementary frame is a triangle, composed of post, jib aad tie. It is embodied both in pieced and in portable cranes, of the wharf, whip, wall, derrick and many other types, and includes cranes in which jibs are curved, or cranked to clear loads beneath. The relative disposition of the three members governs their relative strength, and these dispositions are controlled by the nature of the duties which cranes have to perform. The magnitude and direction and nature of the forces in a triangular frame are shown in Fig. 1. This is the most common type, called the raking jib arrangement. The diagram is only correct when the load to be raised on a single chain and the line of same, from the head pulley to the drum, coincides with the centre of the tie. This type is used for variable radius. The load A runs over a fixed pulley, at the top of the jib B, the radius R of which is unalterable, except by derricking. No trolley nor jinney can run along this crane to vary the radius of the load lifted; hence the reason why many of these are made to derrick. That is, the jib is hinged at D in order to permit of effecting variations in the radius of lift, accomplished both in the derrick cranes proper and in many ordinary cranes that differ from the true derricks in most details, excepting in the capacity for this particular range of movement.

The post, pillar or mast, as it may be termed, is a vital element in all triangular framed cranes, with those few exceptions in which a wall depends on fulfilling the function. The stability of a crane depends in the first place on that of the post. If this fails, it will do so either by breaking off at or near

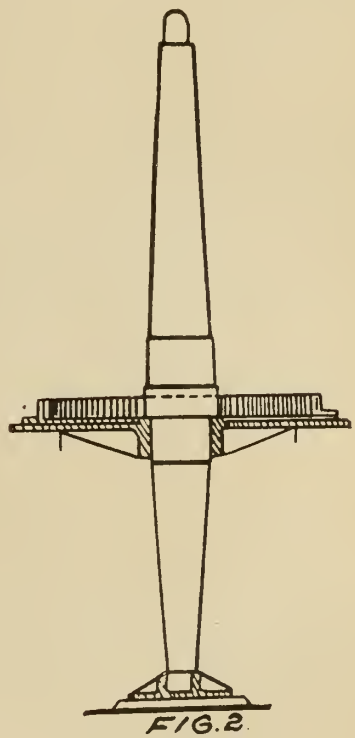

FIG. 2.
Wharf Crane.

the ground line, where the maximum bending stress occurs in cranes that are supported in a footstep only. In cranes that have top pivots in addition, the post would fail somewhere between the top and bottom pivots—a determining factor in which would be the locality where the jib happens to be stepped into the post. From this point of view the nearer the jib is brought down to the ground line, the better, though having regard to the racking of loads inwards, this is the least favorable position. Posts are made of timber, cast iron and steel, sometimes wrought iron, either solidly or built up like girder work. Fig. 2 shows a solid post built up of steel or

wrought iron, as used in wharf or warehouse. Jibs, struts and ties are grouped together because they are mutually dependent. A jib, with a few exceptions, is not self-supporting, but is sustained by ties or with struts. From this point of view various forms of jibs become grouped naturally under three broad types—the cantilever, strut supported, and the tie supported. The first are not numerous, the second only moderately so; the greater number of examples come under the last-named head. Cantilever jibs are used chiefly on some forms of long-armed cranes, usually of the traveling type, with or without provision for rotation, as on the Brown cranes and related types. Having no extraneous support, they are built of girders of semi-parabolic outlines.

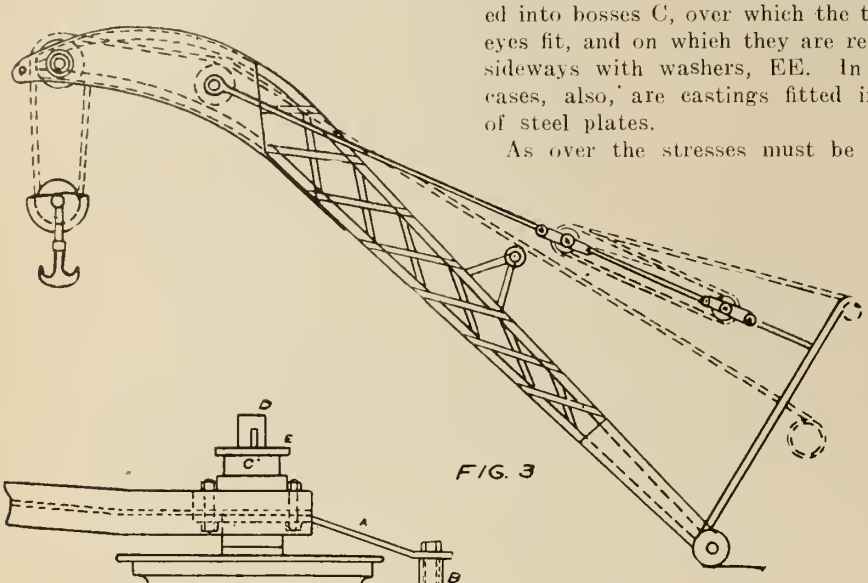

FIG. 3

Crank Jib Crane.

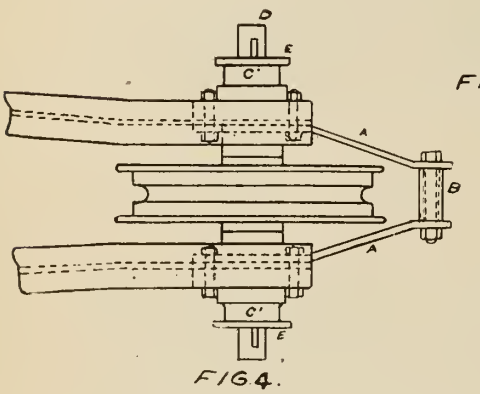

FIG. 4.

Jib Head.

Under traveling cranes there is included all those which come under the class of overland travelers of Goliaths and gantries. The term is applied exclusively to these, notwithstanding that the portable cranes with trucks travel on rails. But the term portable, or the term locomotive, also applied to these, distinguishes them from the traveling cranes. The distinction is purely conventional, but is always understood. There are a number of designs, as those which exist in the frames of traveling cranes, and are too numerous to make mention of all of them.

Fig. 3 shows a cranked jib which is laced, and is of a composite type, in which the fitting of the rods at some distance away from the end leaves the portion between the anchorage and the foot in compression, while the length beyond the anchorage is subject to bending as a cantilever. This jib is widened at the dividing section to afford strength to the cantilever end.

In Fig. 4 a simple jib head fitting for a chain pulley is shown. Two pieces of steel plate, AA, are bolted between the H sections, and cranked to receive a distance piece, B, which also prevents the chain from jumping outside the pulley pin D. The castings are prolonged into bosses C, over which the tie rod eyes fit, and on which they are retained sideways with washers, EE. In many cases, also, are castings fitted instead of steel plates.

As over the stresses must be translated through truss rods, timber of reasonable depth alone is sufficient. The method of trussing, moreover, affects the result. A truss may be simple; see Fig. 5. Then the weight of the girders themselves, and of the crab and its load, and its position, has to be considered. The length, also, of the wheel base D affects the stresses on the end cradles C. Stresses on the wheels and their journals are calculated, as indicated in Fig. 6. Each wheel is taken as loaded with half the load of the main girders, and is wholly in compression.

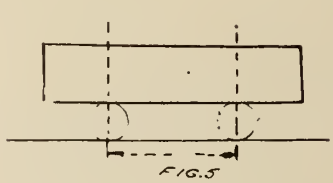

FIG. 5

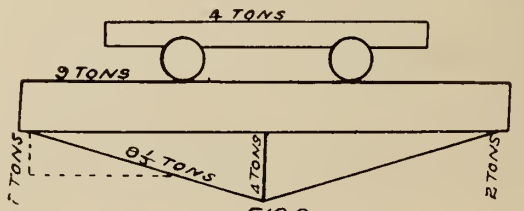

FIG 6

The stress on wheels, due to cross working of the frames, sometimes causes their axles to grind hard in their bearings. This may be eliminated by making the axles fast in their bearings and letting the wheels run loosely on them. The employment of iron and steel for traveler frames affords scope for a large variety in design and dimensions. They are suitable alike for travelers, the power of which ranges from half a ton to a hundred tons or more. Iron is, however, as already remarked, little used now, being mostly displaced by steel.

In use it might be supposed that over much attention has been given to the co-relation of material to stresses; it is well to point out that the question is less one of cost than of weight. It costs more to build up girders than to use rolled joists. It would generally cost more than the value of the metal saved. But that is hardly the point at issue. The dominating fact is the reduction in the dead weight of the traveling crane. By lessening this the stresses on the traveling wheels and axles are lessened, and less power is required for operating—a point of much importance with high speed travelers, which are now so common.

Girders are not quite so simple a matter as this. In designing there are two points which have to be settled—rigidity depthwise, that is, as opposed to buckling or crumpling, and rigidity sideways, to assist the lateral stresses, which are produced by the rigid longitudinal movement of the crane.

THE HUMOR OF STRIKES.

"I see th' strike has been called off" said Mr. Hennesy. "Which wan?" asked Mr. Dooley. "I can't keep thrack ix thim. Somebody is sthrikin' all th' time. Wan day th' horseshoers are out, an' another day th' teamsters. Th' Brotherhood iv Molasses Candy Pullers sthrikes, an' th' Amalgymated Union iv Pickle Sorters quits in sympathy. Th' carpinter that has been puttin' up a chicken coop f'r Hogan knocked off wurruk whin he found that Hogan was shavin' himself without a card fr'm th' Barbers' Union. Hogan fixed it with th' walkin' dillygate iv th' barbers, an' th' carpenter quit wurruk because he found that Hogan was wearin' a pair iv non-union pants. Hogan wint down town an' had his pants unionized an' come home to find that th' carpinter had sthruck because Hogan's hens was layin' eggs without th' union label. Hogan injooced th' hens to jine th' union. But wan iv thim laid an egg two days in succession, an' th' others sthruck, th' rule iv th' union bein' that no hen shall lay more eggs thin th' most reluctant hen in th' bunch."

Boring Bars and Cutters

By JOHN EDGAR

Of the many operations that the machinist performs, the operation of boring is one that requires an amount of skill seldom called into action in the performance of any of the other machine shop operations. The boring of a hole calls for accuracy in more than one direction. The hole must be straight, of a standard size, and must have a degree of finish depending on the class in which the job ranks.

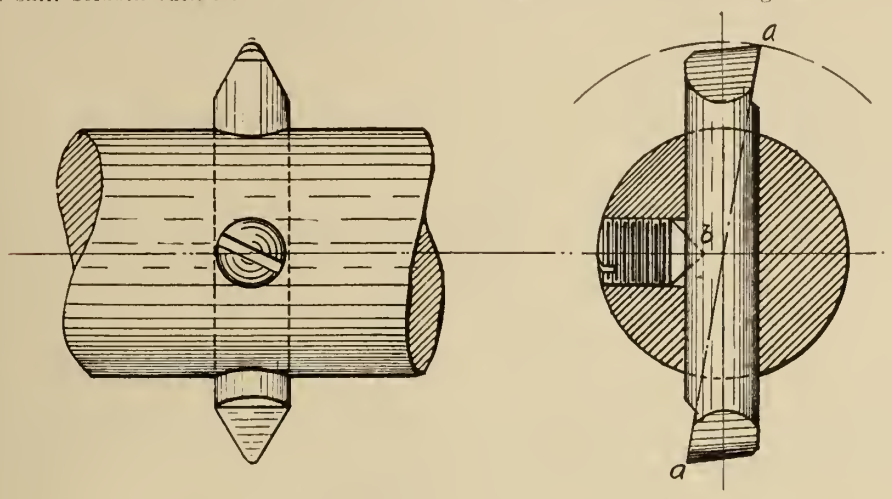

Fig. 1—Simple Round Cutters.

Where the equipment is poor the deficiency must be made up by an excess of skill on the part of the operator. A job of boring cannot be rushed. The best of facilities are not always at hand for the proper handling of the work. Makeshifts are often necessary.

Were one to try to describe the many variations in which we find this operation performed, he would have contracted a very big job. The best that can be done is to skim a "little off the top" and present what may be called the cream of the many methods practiced.

Boring may be accomplished on a standard boring machine, which may have a horizontal spindle or it may have a vertical spindle. The class of machine which we will deal with will be those in which the operation of boring is done with a boring bar, and cutters set in this bar. The operation as performed in a lathe on the boring mill, where the work is made to revolve about the axis of the hole to be bored, does not call for a bar in the common sense of the word, but the hole is enlarged with a boring tool and is what we may call internal turning, to distinguish the two methods.

In the operation, as we are here considering it, the bar is made to revolve and is supported at both ends; one end may be supported in the spindle and the other in a tail support, or both ends may be supported in supports independent of the machine or spindle. In the latter case the bar is given its motion by means of some flexible connection with the spindle. This connection usually consists of two pairs of universal joints.

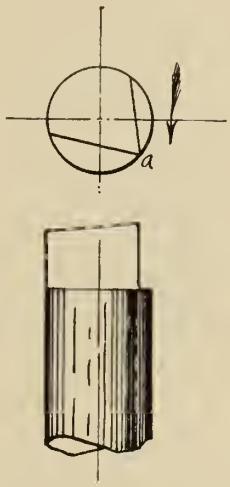

Fig. 2—Simple Boring Cutter.

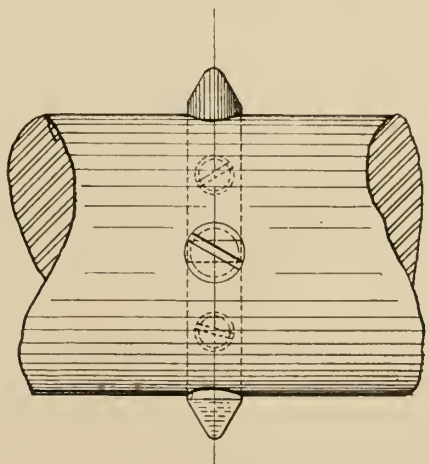

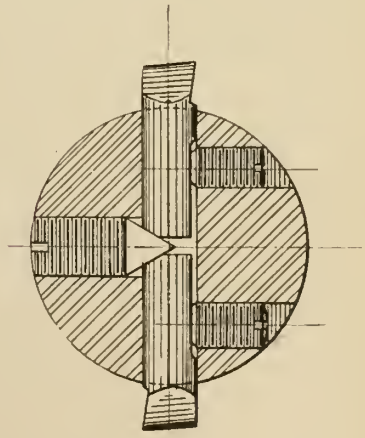

Fig. 3—Adjustible Boring Bar Cutters.

Boring bars may be classed in two divisions, viz., general utility bars and special bars.

The first class may be said to cover all bars that are made for general work, and may be also classed with other handy shop tools. We will not deal with this class to any great extent, merely referring to it in the discussion of the more important class, that of special bars.

The second class is that in which we place all bars that are made up to do one job correctly and to the best advantage, without the necessity of spoiling its effectiveness on one job in order that it may be of use on a general run of work. It may be used in connection with a boring jig, in which the bar is supported by means of suitable fixed bushings, or it may be used as a boring bar, pure and simple.

When a boring bar is to be used in conjunction with a jig, the bar generally runs in hardened steel bushings. Great care must be used in the handling and sufficient lubrication must be supplied in order that the bar does not rough up and seize in the bushing. In order to avoid this, the bar must be kept free from dirt and a generous supply of heavy vaseline used as a lubricant. Any —even the slightest—bur on the bar will be sufficient to cause trouble from this source.

To overcome the tendency of the bar to stick in the bushings when used as above described, the bushings are sometimes made to run in the fixture and are splined to the bar and made to revolve with same, the bar being free in a direction parallel with its axis. The bushings in this case are made with an external taper and are provided with chich nuts on each end so that they can be adjusted lengthwise, to take up any wear that is liable to appear. This

style is not apt to be of such a degree of accuracy as the stationary bushing, because the wear on the cast iron housing would be much greater than would occur with the steel bar and the hardened bushing. However, the freedom from the tendency to seize may in some cases offset the small inaccuracy that might be present. This method of support is well worth looking into, and could be used in many cases where the other style is at present used to a disadvantage.

The simplest form of boring cutter is shown in Fig. 1. This is made of a piece of drill rod and shaped at each end as shown. The length is left a trifle longer than the size of the hole, and the cutter is then placed in the bar and the set screw spotted, and a chip is taken off the ends in the lathe to bring them central; it is then backed off with a file and hardened. The hardened cutter is then stoned to obtain the requisite cutting qualities.

Fig. 2 shows a variation in the cutting edge. This style is much used and is equally common with that shown in Fig. 1. These cutters are, of course, useless after dull, as they lose their size in sharpening. It is well to have a good supply of cutters on hand, where a bar with this style is to be kept at work.

Fig. 3 shows a bar fitted with adjustable cutters. The cutters in this case are single pointed affairs. The adjustment is obtained by the movement of the cone-pointed screw, which acts on the beveled surface on the inner end of the tools. The cutters are held in place by the set screws, as shown. To adjust the cutters, the set screws are loosened up a little, but still have considerable binding pressure on the cutters; the adjusting screw is then screwed inward, forcing the cutters outward an equal amount, so that each cutter still takes its share of the cut. This style will be useful where one is fitting a hole to a shaft or plug and where the holes vary in size a trifle in each separate case.

one would have to use to pass through a cored hole would be of such a size as to be very weak and springy. Fig. 4 shows a suggestion of a way in which the conditions may be altered so as to obtain a stiffer construction of the bar. The bar in this case is made with two sizes. The leading part, that is that

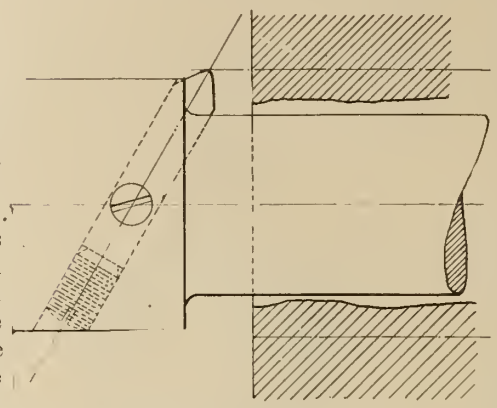

Fig. 4—A Single-pointed Boring Cutter for Small Cored Holes.

part which leads the cutter and has to pass through the rough hole, is made as small in diameter as is necessary,

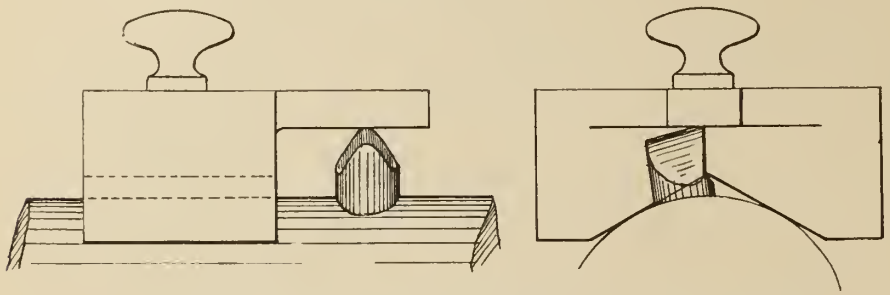

Fig. 5—A Fixture for Setting Adjustible Boring Bars to Size.

while the part of the bar that follows the cutter is made nearly as large as the hole when finished, leaving a small space for chips. This style bar will cause trouble from the interference of the chips unless care is taken to keep the hole as clear of them as possible by the frequent use of the blower. As seen, the cutter is a singled-ended one, and is set at an angle through the bar, the cutting point coming through at the shoulder formed by the larger diameter. This cutter is adjustable for size, the adjustment being made by the movement of the screw set at the end. The cutter is held in position by means of a set screw as in the case with the cutters in Fig. 3.

When adjustable cutters are used and the job requires that the holes be of one size within certain limits, a gauge similar to that shown in Fig. 5 will be found to be a handy tool. This gauge, as seen, is set on the bar, and the cutter adjusted until it comes in contact with the under side of the projecting lip. The use of a piece of tissue paper or a piece of sheet steel which has been hardened, ground and polished in the setting, will insure greater accuracy. The paper or steel is used as a feeler to test the pressure of contact between the cutter and block. It is understood that settings cannot be transferred from one bar to another without the necessity of having both bars of exactly the same diameter.

When a bar is to be used to any extent, on one job, the inconvenience of the round cutters described in Figs. 1 and 2 losing their size so rapidly, is one well worth trying to overcome. This is done in the style cutter shown in Fig. 6. This bar is much more expensive to construct, but where the extent of its use is great, the extra trouble is soon paid for in the better results obtained.

The cutter used is made of flat stock, which may be of either the high speed variety, or of the ordinary carbon stock. It has been proved that the former holds its edge much longer in cast iron than does the latter. The cutter is let into the bar by the slot,

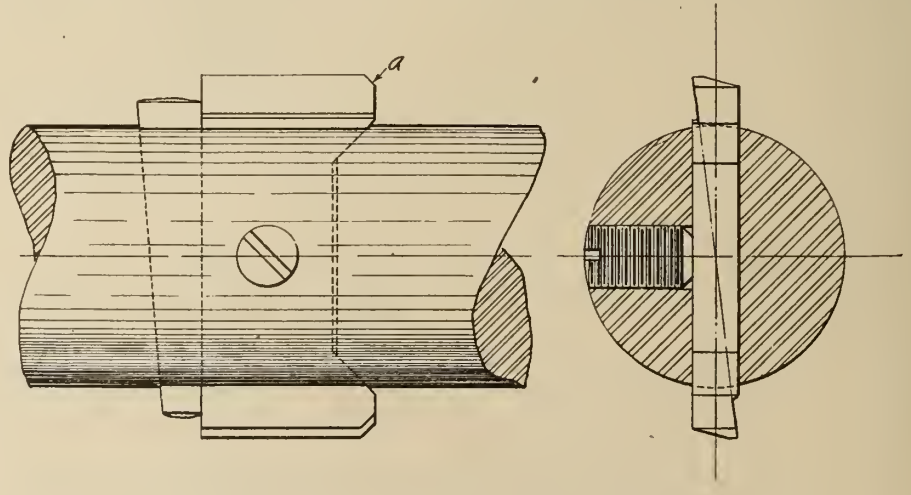

Fig. 6.—A Self-centering Boring Cutter.

which has the front end beveled at the periphen of the bar and the rear end is tapered to accommodate the wedge used to force the cutter home against the bevels. The bevels centre the cutter with the axis of the bar. The cutter is further secured by means of a set screw

which passes against the side of same as shown.

The advantage of this style cutter is in the length of the cutting edge. The boring takes place at the front end at slot. This design should not be any more expensive to carry out than that shown in Fig. 6, and has some points in its favor that do not appear in the former design.

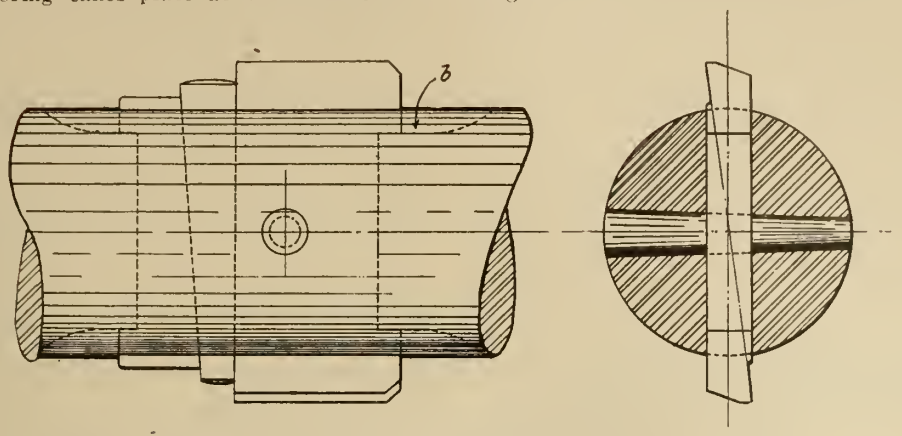

Fig. 7.—An Elaborate Design of Boring Bar with Flat Cutter.

(a), and the cutter that follows smooths out the hole and acts as a reamer in bringing it to size. When the cutter becomes dull it is sharpened by grinding the face (a). The cutter is fitted to the bar and then turned to grinding size in the lathe, then backed off by hand with a file or by milling in a milling machine. It is then hardened and the cutting edge ground and stoned to a fine cutting edge. The front of the cutter is either shaped as shown, to give it a radial cutting face, or it may be left parallel with the blade, giving the cutting edge a negative rake, producing a scraping cut, which may be of advantage on some work, as, otherwise, the tendency is to chatter, due to the broad surface in contact. This style cutter produces results that cannot be found fault with.

Fig. 7 shows a variation from the style previously shown. There the slot is square with the sides of the bar. The cutter is held central by means of the shoulders formed by milling into the bar, as shown at (b). A double wedge is used, which forces the bar against the opposite end of the slot. The taper pin is used as a precaution in case the wedge should become loose. Some means might be made for holding the wedge in place, such as a set screw.

This design is much more expensive to construct than that shown in Fig. 6, but it has its admirers and is well worth investigating.

A means of holding the flat cutter is shown in Fig. 8. In this case the cutter is forced against its seat by the threaded collar. The collar is checked in position by the set screw, which presses the soft metal plug against the thread, checking any movement of the nut without injuring the thread on the bar. The centreing seat for the cutter is obtained by either filing or milling a flat on the bar at right angles with the sides of the

Steel is not the only material that is used for boring tools. Sapphire is often used when boring babbitt and other soft bearing metals. The sapphire stone is set in a holder and is shaped as in Fig. 9, which is a view looking at the face of the point. The diamond is also used as a boring cutter and many are used to cut materials that are hard enough to ruin the best of steel tools. It is set in a holder in much the same manner as in the case of the sapphire point. Fig. 10 gives a suggestion of how it is held.

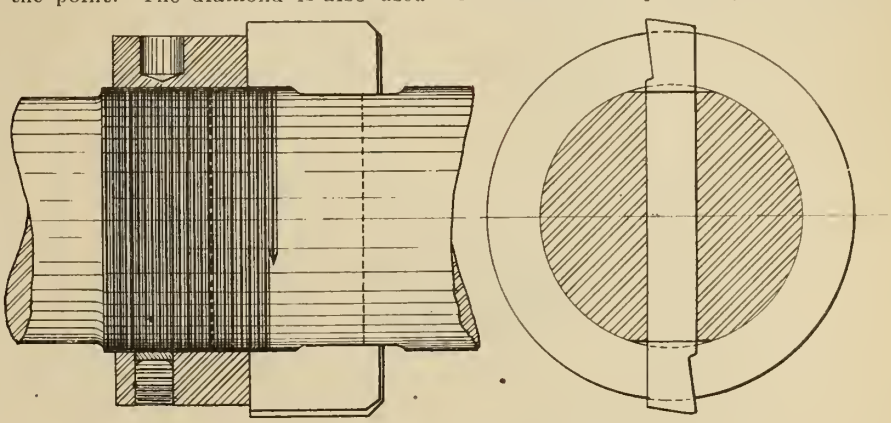

Fig. 8.—A Simple and Reliable Cutter Bar.

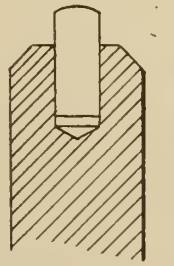

Fig. 9—A Sapphire Cutter-holder.

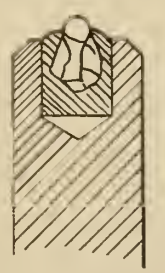

Fig. 10—A Diamond Cutter-holder.

As mentioned in the beginning, boring is an art that may be made to attain a high degree. It calls for skill that would be but wasted on other operations. It may be said to be the king of machine shop performances. To be able to set up a difficult job and accurately bore a number of holes in same so that each one holds a proper relation with its neighbor and also with other important features of the main casting, is quite a trick. It becomes a fine art when the holes must be kept to a standard and when facilities are not of the best.

METHODS OF ANNEALING NOVO STEEL.

A great many times a machinist wants to use a piece of Novo steel for some special job, but, not having a piece that is soft enough to work, he uses carbon steel instead, generally because he does not know how to anneal high-speed steel, and imagines that an elaborate heating system must be used. I have met dozens of blacksmiths, tool-dressers and machinists, who declared that the thing was impossible, but who quickly changed front when shown how. Not long ago, a writer in one of the prominent mechanical journals, who said he had done nothing but worked with steel all his life, described his process of annealing Novo steel. He packed it in a tube or iron box in ashes, clay or charcoal, put it in the furnace, and kept it at 800 degrees F. for five hours, then at 900 degrees F. for seven hours, and then he let the fire go out. He removed his steel from the furnace twelve hours later.

This method seems rather inconvenient, however, and the writer would propose the following: If you have a piece of Novo steel that you want to soften so that you can drill, file or tap it, get a barrel of old slacked lime and a piece of pipe, threaded on both ends. Get a pipe large enough to allow the steel plenty of room. Put a cap on one end and put in about an inch of lime at the bottom, drop in the steel and pack lime around it, keeping the steel in the middle of the pipe, and fill the other cap with lime and screw on. It will be

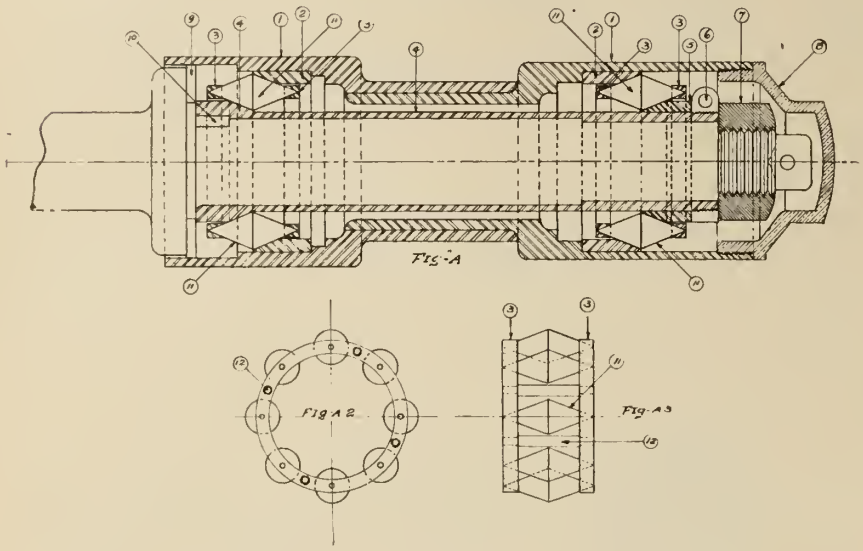
well to explain here that the whole secret of annealing this or any other steel is to keep it from coming into contact with the air and thereby chilling while in the process of cooling.

Next put the pipe and contents into the fire, and heat slowly and evenly to a white heat, then take out the pipe and bury it quickly in the middle of your barrel of lime and leave it twelve or fourteen hours. For ordinary sized pieces the time taken to heat will not be over twenty minutes, and if you have a good-sized forge, it will be considerably less. Be sure the steel is heated through before taking it from the fire. I have annealed hundreds of small pieces of Novo steel in this way, and have never yet met with a failure.—E. Viall, in Machinery, N.Y.

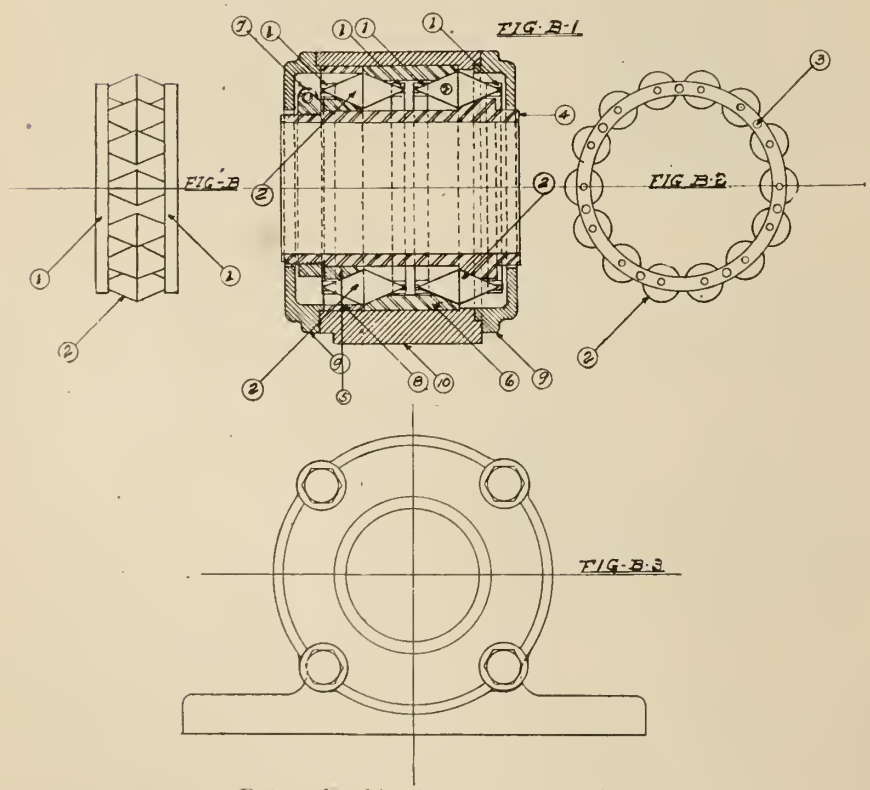
Patent Double Cone Roller Bearing

A new style of bearing patented by J. Dove Smith and F. E. Lauer, Niagara Falls, Ont.

By F. E. Lauer.



Patent Double Cone Roller Bearing.



Patent Double Cone Roller Bearing.

The following is a description of this bearing as applied to a wagon axle and pillow block:

Fig. A shows the drawing of a wagon axle bearing, in which I, is the boxing which presses in the hub of the wheel, and is made of mallable iron; 2 is the outside band made of steel tubing, hardened and ground; 3 and fig. A-3, the cage rings which carry the rollers; 4 is a steel sleeve made the full length of the bearing, keyed a sliding fit to the axle end, and which carries the inside path of the bearing; 5 is the adjusting path, which is controlled by the locknut 6; 7 is a cast iron nut which allows the wheel and bearing to be taken off without disturbing the bearing, which is self-contained; 8 is a brass dust-proof cap; 9 is a fibre washer and used as a dust washer; 10 is the key which allows the sleeve to move laterally, but not around; 11 and fig. A3, are the rollers; 12, fig. a-2, and fig. a-3, show the tie rods which hold the cage rings with the rollers together.

The principle of the bearing is that the load bears on one side of each cone of the rollers, and as the opposite side of the cone of each roller does not touch anything, hence does not serge, when the wheel revolves it carries around the boxing 1-fig.-a, also the outside path 2-fig.-a, which in turn revolves the rollers which roll on the inside sleeve 4-fig.-a. The adjustment for wear is taken up by the lock nut 6, which engages the adjusting path 5. It will be readily seen that this bearing handles end thrust, or lateral motion perfectly, as the pressure is being always exerted against the paths of the inside sleeve, which are of the angle coinciding with the angle of the roller, and which demonstrates that lost motion will be taken care of mechanically itself.

Pillow Block Bearing.

Fig. B-3. and B-1, shows the plane and section view of a pillow block bearing, or truck bearing, in which fig. B-1 and fig.-B-7 are the cage rings; 2 fig.-b. and b-1 are the rollers 3 fig. b-2, are the rods, for locking cage rings and rollers together; 4 fig. b-1 is the inside sleeve and revolving path; 5 fig. b-1 is the adjusting path; 6 fig. b-1 is the outside path; 7 fig.-b-1, is the adjusting nut; 8 fig.-b-1, is the spacing piece to prevent lateral motion of outside path; 9 fig.-b-1, is the bearing caps; and 10 is the main body of the bearing.

The motion in this bearing is the reverse of the wagon, axle bearing, as 4 fig.-b-1 revolves with the shaft in a pillow block bearing, or with the axle of trucks, which, in turn, transmits the load through the rollers to the resisting and outside path 6 fig.-b-1. Fig. 1, is a plane view of the cage rings and rollers, and fig.-b-2 is an elevation view of cage rings and rollers. All working parts of these bearings are hardened and ground so as to insure proper contact and results.

Preparing Work for the Grinding Machine

A Treatise Showing the Practical and Economic Use of the Grinding Machine for the Finishing of Work in the Machine Shop.

By H. DARBYSHIRE.

The amount of stock to be removed by grinding is in the first place dependent upon the class of machine employed, and if this be of a light type the grinding allowance must be as small as possible and the previous machine-work must be produced by highly skilled labor.

Here we have the least economic side of grinding for, in addition to the higher cost of labor for previous work, the time taken in grinding by reason of the

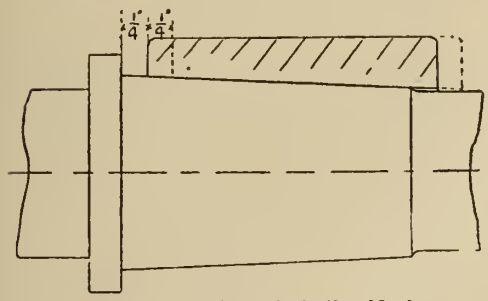


Fig. 1—Conical Spindle Neck.

narrow wheel-face and slow feed, is greater than otherwise necessary. Where, however, machines stand on a good foundation, thus preventing vibration, the actual grinding is done more quickly, and the question of cost of previous labor for the most part resolves itself into one of organization. A rapid means of grinding allows us to give the previous machineman a greater tolerance and to increase his output, or a cheaper class of labor may be employed. With the present day results obtained by the use of high speed steel, it is absurd to assert that the grinding wheel is its superior in removing stock, but the assertion may be qualified by saying that it is superior where the amount of stock to be removed is limited, taken in conjunction with the better results obtained. At the present time it is a disputed question among engineers as to whether high speed steel is suitable for finishing purposes, but even where it is successfully used the finish obtained cannot be compared for accuracy with ground work, and we may affirm that where good work is required, grinding must be resorted to. Given this, we may next consider what conditions are involved that affect the matter from the point of view of economy. Excessive grinding allowances mean a greater amount expended in wheels; fine grinding allowances entail a high cost of labor for previous work, and a risk of work not cleaning up to finished dimensions; therefore, most of the question depends on the class of labor employed in preparing the work, and the limit of error a man can be depended on to work, too; if we take .015 inch to .025 inch for a general grinding allowance where machines are powerful and rapid, we may be said to hit the medium between lowest cost of wheel and previous labor, and this latter would be very poor if it could not be trusted to work safely to this limit. Some departure from the limit given would be sometimes necessary for safety, more especially for hardened work of peculiar shapes, but the amount to leave here must be arrived at by experience.

Long cylindrical pieces are ground more cheaply and safely from black stock up to a diameter of about 2 inches, and even above that size it is much cheaper than turning and grinding if bars were straight and the amount to be removed not about 1-16 of an inch.

We may take a case to illustrate this: A black bar, 2 1-16 inches x 10 feet, would be reduced to 2.015 inches in half an hour in a modern machine, and finished outright in a total of one and a quarter hours by a man with some little experience; this same shaft, if it had been previously turned to 2.020 inches, would probably take the same or longer time, and the reason is not difficult to understand.

In the first case, the operator can attack the piece with confidence, because he knows that the heaviest cut he can take will not lead him into error, and while the main body of the stock is being removed, he is both making all necessary adjustments and obviating all the little precautions which are necessary but somewhat inexplicable when previous machinery has been thought necessary. On the other hand, where the piece has been previously turned, he is alive to the fact that this turning has induced little crooks or bends to develop, and (though hidden in the straightening necessary before grinding), they are liable to develop themselves at any moment, and so his depth of cut is so limited that it may be termed, on the whole, a kind of semi-roughing, and the caution which is necessary is an expenditure of time which had better have been utilized in substituting the grinding machine for the lathe. There should be a constant understanding between the grinding and machine departments, so that the work may be prepared in such a manner as to be adaptable to the grinders' facilities for holding or chucking it and this applies mostly to cylindrical work, and more especially when it is prepared in the turret lathe. For example, bushings that must be ground externally and have a clearance hole, should have this hole true within certain limits, and be bored to a standard size so as to accommodate the grinders' arbors.

It is a mistake to finish one portion of a piece of work in the lathe and the other in the grinding machine; errors in concentricity are the result, and the contrast between the two parts make it look like a slovenly job. This is sometimes excusable where the grinding is costly, as in the light type machine, but with a properly constructed machine it is far cheaper to grind even if the parts are finished for appearance only, and a better result is obtained.

Grinding a Taper.

In preparing taper work for grinding, errors which are the result of want of thought often creep in, and sometimes

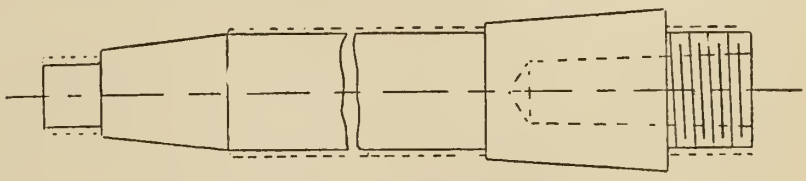

Fig. 2—Roughing Spindle for Hardening.

with disastrous results. Work which has been carbonized may often have so much stock left for removal (through want of thought), that all the hardened surface is ground away before finished dimensions are reached, and yet a little calculation of an elementary nature will quickly decide the right grinding allowance. Fig 1 is a conical spindle neck, and the ring gauge A must come to distance shown from collar when finished; the whole rise in taper is 1 inch in the foot and .020 inch-1.000 inch= 50, and the distance to let the ring

*Extract from H. Darbyshire's book on "Precision Grinding," published by Hill Publishing Co., New York.

gauge up in turning would be 1-50 of a foot added to the distance shown in sketch, or about ½-inch, roughly speaking. It is within the writer's experience that many lathe hands look on all tapers as being adaptable to the same grinding allowance, and let their ring gauge up to a certain distance, irrespective of the rise in the taper; it is a stupid error, of course, and would be prevented if shop drawings had these limits plainly marked.

The same may be said of cases in which special grinding allowances must be made for distortion in hardening or for depth of carbonizing, and, after experience has proved what is the amount to leave, the proper dimensions could be shown on the drawings. Some of these special cases are more a matter of supervision and of the laying out of work, and we may give an example.

Fig. 2 is a spindle which must be carbonized on its taper-journals only; the front end must be threaded and bored after hardening; if it were turned all over within a limit of .020 it would probably be bent so much that it would not clean up to size, nor would the front end be soft enough for the threading and borning tools; but if prior to carbonizing we leave a larger amount, as shown by dotted lines, and turn the journals only with a grinding allowance, we can first straighten on the soft portion in the middle or draw the centres, if necessary, and turn to grinding size, then rough grind all over and down to soft metal on the front end; after this we can bore, thread and finish grinding.

Care in Hardening.

The preparation of hardened work for grinding is a subject that will bear some careful consideration; nothing is more annoying than to find a piece of work over which much valuable time has been spent unfit for the purpose it was meant for after the hardening operation. Work may be so bent or distorted as to require straightening, and then we have the ever present danger that it may resume its crooked form after still more time is expended in finishing; yet this is only too often the result of a want of some reasonable care in preparing the steel. It is, of course, impossible to foresee what is going to happen in any case when hardening is concerned, but much trouble may be averted by systematic annealing; a piece of steel as it comes from the mill or forge is always liable to contain hidden strains that can only be released by reheating. When a piece of work is made from bar steel it should be centred and straightened as true as possible. This is necessary, because the bar in its rough condition is decarbonized for an uniform distance below the surface. The straightening should not be done cold, as this only leaves opposite and antagonistic strains on two opposite sides, and these may release and cause warping in the hardening process. After the bar has been heated to a bright red, it may be straightened and then a cut taken over it to remove all the outer surface. It should then be carefully annealed, and if it comes out fairly straight, it may be machined to within the grinding allowance; if, on the contrary, it should be badly crooked, the annealing process should be repeated after it has been again straightened out. The object here in annealing is to make sure that all strains which are developed in the rolling of the bar are removed, and until this is done it is not safe to proceed with the work; and the reason we take pains to make the bar quite true in the first case, is to ensure that its surface is homogeneous.

It is necessary that all keyways be cut before grinding, and apart from the question of distortion and the damage which may be done by handling, it is another instance of the advantages accruing from grinding. We cannot finish work in the lathes where keyways are present, so they must be machined after the cylindrical finish; this springs the work slightly, and it will not run sweet without straightening, which sometimes means damaging the piece, and, in any event, entails extra care and time on the part of the operator; then the burrs must be removed from the keyways with a file, which disfigures the work and costs money for files and time. On the other hand, if we finish the parts by grinding we may do all this work previously, and the springing from keywaying is rarely more than what the amount left for grinding will cover, so that we save straightening, files and time on each piece a considerable economy, and we also get a far better finished result. What we mean by distortion in keywaying is, of course, due to the stress on two sides of a piece of work being disturbed through removing a portion of the metal on one side, the bend developing on the side opposite to the keyway.

Whilst on the subject of keyways, it may not be out of place to advise the grinder to look out for errors in any piece he may have to grind with a key inserted. If it is tight on the ends it will spring the piece over in the opposite way to that which has just been described.

Where there are shoulders with square corners they should be slightly undercut below the finished dimension or else squared out in the lathe after grinding; as it is preferable to have the grinding operation last of all to prevent danger of damage to finish, undercutting is better when possible, and for internal work where the holes are blind or have shoulders the same applies. Where there is a small radius the wheel will conform to its shape, and it may be finished before grinding; but when the radius is large it is more economical to get it out in the lathe. If we have to turn a large radius on a wheel, it imperils the diamond tool, and we have to waste a great deal of the wheel in bringing it back to its flat face. Hardened work and special cases may prove an exception to this rule, but they generally warrant the expense necessary in providing a special wheel and the time required for changing it. Where these cases do occur, the radius must first be turned good and as little material left for removal as possible, or the wheel will lose its shape.

Where large radii are to be very accurate and the material is not hardened, we may compromise by making a special fixture for finishing them with a spring tool in the grinding machine after the parallel portion has been ground, care being taken to catch the chips if large; this has the merit of saving time otherwise occupied in transporting heavy pieces back to the lathe, such as car axles and lessens the danger of damage.

Have Standards of Grinding Allowance.

To assist the grinder as much as possible, it is desirable that some uniformity be present in the amount of grinding allowance where there are a number of duplicate pieces; it will save him much time in stopping to take dimensions and enable him to gauge his wear of wheel and make compensation for it in working.

The same uniformity in lengths will absolve him from the necessity of adjusting his stops or dogs for each piece, and so allow him to work more expeditiously, and it will lessen the danger of his running into shoulders to the damage of his wheel, the work, or himself. Both these points have some reference to an always desirable method of manufacturing, which may be much simplified by providing mechanical means which will ensure the requirements stated being easily obtained within close limits, and where possible it is well to adopt them.

In the preparation of cylindrical work for grinding or lathe work, the centre holes should be the first consideration; it is the foundation of quality in anything that pertains to accuracy. It is an instance of one of the inconsistencies in the engineering trade that the matter of centres often receives little attention, many who look for and demand good work seem to look on this important point with indifference; stabbing the end of a piece of work with a centre

punch is a method frequently used and is little more primitive than the use of that abominable tool the square centre. When these methods are practiced, it is seldom that angles are kept uniform, because they depend on the individual even if gauges are provided; it costs no more to make a good centre hole than a bad one, and if proper tools are provided, it costs less; these would consist of properly made centring drills issued and controlled by the toolroom. The facing of the end of work when centred is also often neglected, though its omission is often difficult to understand; when it is not done, it is unreasonable to expect to turn out work which is round and true.

The grinding machine is not a machine that is likely to lead to the displacing of other machines, but rather to add to their utility or lead at most to a change in their design; it has superseded the engine lathe in many instances, but has made the high speed lathe and turret lathe more serviceable

Fig. 3.

B. Ground outright from 1 5-16 inch black steel bar in 50 mins. } .0005 inch.
C. Material 1 7-16 inch black steel bar, end roughed down in turret lathe in 16 mins., afterwards ground to a limit of .0005 inch in 82 mins. Total time, 98 mins.
D. Material 1 11-16 inch black steel bar, end roughed down in turret lathe in 18 mins., afterwards ground to a limit of .001 inch in 70 mins. Total time, 88 mins.
E. Material 1 5-16 inch black steel bar, ends roughed down in turret lathe in 14 mins., afterwards ground to a limit of .001 inch in 62 minutes. Total time, 76 mins.

and desirable, the former, because the grinding machine will accept and finish work from it that has occupied it less time than was formerly the case, for let the surface be turned at any pitch or the surface be ever so irregular, it will remedy these defects more quickly and with better results than is possible by any other known means when accuracy of work is necessary. Used in conjunction with the turret lathe, it has developed the utility of that valuable machine and given an impulse to its design and manufacture which is entirely profitable to those who adopt it.

Many pieces may be quickly machined from plain black stock by using the turret lathe for making the larger reductions on the ends and leaving a safe margin for grinding, of which a few examples are given in Fig. 3. When locking threads are necessary on the ends they may be returned to the turret lathe to be screwed after grinding, and then any round corners left by the wheel may also be squared out if necessary.

The grinding allowances for plane surfaces may generally be less than for cylindrical, and, in the case where there is no water supply to the machine, they must be so. For hardened work, experience alone can be the guide. Where the grinder has no magnetic holding appliances it is better to machine some small pieces in long strips and cut off to proper lengths afterwards, this, of course, where their shape will allow of it. Let all drilling, slotting, and chipping, or other operations be prior to grinding, and, where possible, contrive that the grinding shall be the final operation. With a properly constructed surface grinding machine, the milling machine may be utilized in a somewhat similar manner to that described for the turret lathe, and some work may be ground from the black if the casting or forging is good. Plain adjusting strips are an example of the latter, or light stampings or castings, where their shape will allow. All surfaces of castings or other parts that are finished bright for the sake of appearance are better done on the surface grinder than by any other means, and the result is a beautiful uniformity of finish, which is no small assistance to the selling of the finished product.

Grinding Cast Iron and the Alloys.

We cannot close this treatise without a further reference to cast iron. Grinding allowances for cast iron must never be too large, for we are compelled by the nature of the material to use a soft bonded wheel, and much waste of wheel is likely to occur if this is not watched. Fortunately it is not so liable to spring in machining as steel is, so that we can afford to work closer, nor is it so liable to tear in machining, but leaves marks with a very shallow depth. As an offset to this a close limit in preparing it for the grinding machine means a higher degree of labor employed, and the discrimination which is necessary for economic working must be more acute. There is a special advantage in grinding cast iron of a porous quality, for the act of grinding seems to close the pores and make the work more acceptable in regard to finish than any other method.

Copper, brass and other alloys should have a fine grinding allowance; the cuttings have some value, more or less, and at present there is no method known of separating them from grinding residue that is of practical value, so they are better collected from the lathe or other machine which may be previously employed.

The grinder should receive his work ready straightened, so that he may not be tempted or compelled to use his machine for the purpose; or delay be caused through waiting for it. Let all hardened work have two grindings, at least, so as to release all hardening strains and to test the under skins before finally finishing. Improved methods of preparing work will make themselves apparent if all departments concerned will co-operate, and the very gratifying results in cheapening the cost of production by grinding methods will only be equalled by the more inviting appearance and accuracy of the collective details and the finished, built-up product.

GRANTED.

A Boston man who just returned from a hunting trip in Maine tells of an experience he had while there.

It was his misfortune to get lost one day, and, to make matters worse, just as a heavy rain set in. He started out in what he thought was the right direction and wandered on through the wet and darkness, finally stumbling on to a narrow road leading in another direction; this he took and presently came to a house. The place was all dark, but he went up and thumped loudly on the door. There was no answer, so he tried again. This time a window went up and a voice growled:

"Well, who is it?"

"A friend," the man replied.

"Well, what do you want?"

"I would like to stay here all night."

"Well, stay there, then."

And the window fell with a bang.

Ball Bearing Design*

A few of the more important results of tests on ball-bearings conducted by the well-known German engineer, Professor Stribeck.

By HENRY HESS.

Sliding bearings wear out by abrasion of the carrying surfaces. Ball bearings do not give out from wear and do not wear. They may be ground out by admitting grit, but that is as illegitimate a condition for ball bearings as it is for sliding bearings.

The only legitimate cause for the giving out of ball bearings is the stressing of their material beyond the limit of

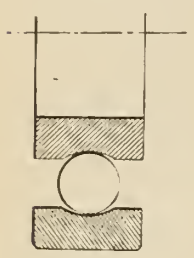

Fig. 1.

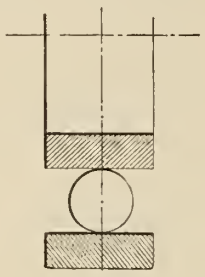

Fig. 2.

proportionality. Lightly loaded bearings can be so designed as to eliminate this cause and so insure practical indestructibility. For heavily loaded bearings this condition is not realizable within practicable dimensions, but the proportions may be so chosen that the over stressing does not result in breakdown within the lifetime of any mechanism to which the ball bearing is applied.

A knowledge of the elastic qualities of the materials at the hardness under which they are used is imperative. It being the elastic behavior that is important with ball bearings as with all other egineering structures, tests of balls, such as are commonly made to determine ultimate rupture when pressed into a steel plate and using the depth of indentation of the plate, or load at which rupture occurs as a measure of ball quality, are not only of no value, but are misleading.

Equations for Load Capacity of Ball Bearings.

The quality of balls and of ball races must be determined from their behavior

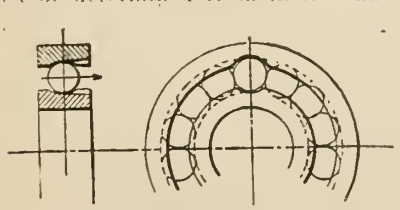

Fig. 3.

under loads in the neighborhood of the elastic limit. Balls may be subjected to loads increasing as the shape of the supporting surface more nearly becomes complemental to that of the ball. i.e., much better carrying capacity is had with a race as shown in Fig. 2 than with a flat one as shown in Fig. 1. This groove, naturally, must never have a curvature equal to that of the ball, since that would substitute sliding for rolling contact.

The frictional resistance of a ball bearing is lower, the less the number of balls. Usually bearings can be designed to have between 10 and 20 balls. The following equations have been deduced from experiments, which will be useful in designing bearings:

$$P_o = \frac{5}{Z} P_b$$

where

P_b = total load on a bearing consisting of one row of balls;

P_o = greatest load on one ball;

Z = number of balls.

The load carrying capacity of a ball is

$$P_o = kd^2,$$

where

d = diameter of ball,

k = constant dependent upon the material and the shape of the ball supporting surface.

From the first equation

$$P_b = P_o \frac{Z}{5}$$

and substituting for P_o from

$$P_o = kd^2$$

gives

$$P_b = kd^2 \frac{Z}{5}$$

Taking one-eighth of an inch as unity, the following table gives combination values of "k" for different shapes of races, both for the material formerly used in Germany for ball making and for the improved steel alloys used later. These constants give the value of P_b in kilograms.

Shape of Race	R=infinity	R=⅔d
k—for older materials	3 to 5	10
k—for imprv'd "	5 to 7 5	15

Here R=radius of the curvature of the ball race; and d=diameter of ball; where R is infinity the race is flat, as shown in Fig. 1. Fig. 2 shows R as 2-3d.

As an example of this, given a ball bearing with a race having a radius of two-thirds the diameter of the balls, having 15 balls each 1 inch in diameter; required the total load which can be carried by the bearing, the improved material being used in the balls.

$$P_b = kd^2 \frac{Z}{5}$$

Substituting values,

$$P_b = 15 \times 8^2 \times \frac{15}{5}$$

(notice that "d" is 8, since the unit is ⅛ in., and the diameter of the ball is 1 in.)

$$= 2880 \text{ kilograms},$$

or

P_b = 6350.46 pounds, since 1 kilogram = 2.205 lbs.

If the centimeter is preferred as the unit for ball diameter, then the value of "k" in the above table must be multiplied by 10, or, more accurately,

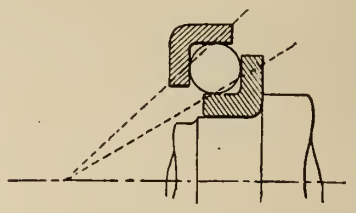

Fig. 4.

9.92 and 1 will be the unit when diameter of ball is given in centimeters, instead of ⅛ in., as when the diameter is given in inches.

Conditions Which Modify This Formula for Carrying Capacity.

Speed of rotation, in so far as it is uniform, does not affect carrying capacity. (This applies to radial bearings, but not to thrust bearings of the collar type; in these the carrying capacity decreases with increase of speed.)

But speed is rarely uniform; variations cut down the carrying capacity; sharp variations of small amplitude, particularly at high speed, have the more marked effect. Their reducing action is similar to the battering effect of sharp load variations.

Load variations reduce carrying capacity, the effect increasing with the amount of the load change and the rapidity of such change.

Accumulated experience with various classes of mechanisms is so far the only available guide for estimating the reductions in the constants k that must

* This report was translated from the German text in full by Henry Hess, and read before the American Society of Mechanical Engineers in June.

be made to take these influences into account.

The carrying capacity of a complete bearing is no greater than that of the weakest cross section that comes under the load. This applies to all those forms which have curved race sections of maximum sustaining capacity, except at a point where an opening is cut to permit the introduction of the balls; such bearings are, as to load carrying capacity, governed by the weaker cross-section at that point.

The calculated carrying capacity can be realized only if all balls sustain their share of the load. It is obvious enough that if a ball is smaller than those on either side of it, it will not carry its share of the load; should it be larger it will carry more than its share and may be overloaded. Uniformity of ball diameter is essential. The permissible variation in ball diameter will be governed by the deformation produced by a relatively small part of the total bearing load, so that the balance of the load may be distributed over the several balls. Such permissible variations of ball diameters amount to

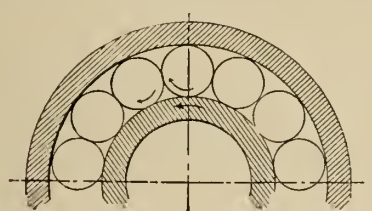

Fig. 5.

but little more than one ten-thousandth part of an inch.

High finish of both ball and ball sustaining surfaces is essential. The presence of grinding scratches will very materially cut down the cited values of the constant k. Of course this presupposes true surfaces underlying the high polish. It follows from this requirement that rust and acid must be carefully avoided, as they are destructive of finish and truth of shape.

It may not be amiss to point out that uniformity of quality of material, of hardness and of structure throughout are essential. The mischief of using balls having different values of k is not simply confined to the individual ball; if, for instance, one ball were materially harder and so deformed less than its mates, it would take more load and might, therefore, overload the material of the race, which would yet be entirely suitable under a division of the bearing load among a larger number of balls.

A good ball bearing will have a coefficient of friction, independent of the speed within wide limits, and approximating 0.0015. This coefficient will rise to approximately 0.0030 under a reduction of the load to about one-tenth of the maximum.

Material Requirements.

Any material can be used that will not, under the working load, be stressed sufficiently beyond the proportional limit as to bring about its destruction before the lapse of a desired working life.

These conditions permit the use of practically all of the materials known to mechanical engineering. With very few exceptions, however, the load conditions are such as to demand steels of the highest grades and these most carefully tempered. For automobile use, no others can be considered. That puts out of the running all merely case hardened materials. In these there is always a more or less sharply defined change of structure at some distance below the surface. Continued working will cause a loosening of the hard shell from the softer core, soon followed by a breaking up and very characteristic flaking of the surface. Usually this flaking is local; its action is increasingly progressive, soon involving the entire bearing.

What has been said of case hardened materials holds true also for those carbon steels in which the hardening is not carried substantially and equally through the entire mass.

What is true and required of the ball material, is even more so for the races. With time, the ball presents its entire surface to the load, the small vibrations and changes of load being sufficient to frequently bring in a new axis of rotation. Not so the race; that is fixed and so always exposes the same surface element to the load attack.

Requirements of a Good Ball.

Truth of shape and size is the first requisite. All requirements will be met if the balls are true to shape within one ten-thousandth part of an inch, and if all the balls used in each individual bearing have a similar small error in size. It must not be inferred that for materials of lower grade, larger inaccuracies are permissible.

Surface finish to a very high degree is also essential. What is usually considered a very good finish, indeed, may be characterized as totally inadequate. The detection of grinding or polishing marks, with the eye or even with a pocket reading lens, condemns balls utterly, that is, for long life under high loads and speeds.

The elastic limit should be high; and the hardness and uniformity of hardness throughout the mass of the ball to the highest attainable degree is essential.

Correct knowledge and uniformity are more important than even these requirements of high elastic limit and hardness. It will not do to say that, though some balls of a lot may do better than others, the design may be based on the poorer ones. That would result in the better balls carrying more than their share of the load, much as and with the same bad effects described while considering truth of shape and size. Lower quality, provided it is uniform, can be allowed for. It will then merely affect dimensions.

Ball making machinery has arrived at a very considerable state of perfection; but balls within a limit of one ten-thousandth of an intended size are not yet being made without the sacrifice of other qualities. That is, however, not important beyond having some slight bearing on cost, since it is perfectly feasible to select and grade balls within the desired limit; but the hardware dealer's word for uniformity of size is not a safe guide; he is perfectly honest in throwing odd lots of ⅜-inch balls into one box and in thinking the customer who objects because they vary a

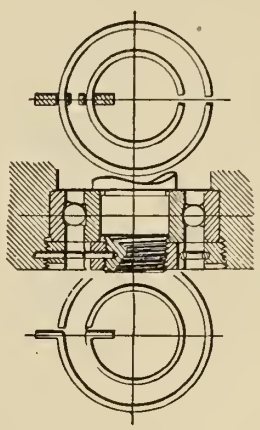

Fig. 6.

half-thousandth, or even two, a "finicky crank."

The Assembling of Balls in Bearing.

Cutting a local groove from the side into a race for the purpose of assembling the balls between the two races is general, as shown in Fig. 3, but is not good practice. If such cut is confined to one race which is then so held in the mounting as always to keep the opening at the unloaded side of the journal, this is at least defensible practice. The carrying capacity is then not decreased, as the load is carried by cross sections of maximum sustaining ability. Unfortunately, this demands the use of two differing designs; the one with the cut in the outer race, the other, with that placed in the inner race, according as the shaft or the housing rotates; the first case is the usual one, of an ordinary journal; the second is found in wheel hubs, etc.

Fig. 4 shows a typical four point contact bearing. In order to secure roll-

ing, the contact points of balls and races should form points of a cone of rotation, whose apex lies in the centre line of the shaft, or they may form points on the surface of an imaginary cylindrical roller that is parallel to the shaft. The defect in all of these forms is their adjustable feature. This places them absolutely at the mercy of every one capable of wielding a wrench; a bearing that has been properly proportioned with reference to a certain load, will be enormously overloaded by a little extra effort applied to the wrench. Or the bearing may be adjusted with too much slack with consequent rattle and early demise. The prevalent idea that these bearings may be adjusted to compensate for wear is erroneous. Wear will form a groove on the loaded side of the race, deepest at the point of maximum load.

It is held by many designers of ball and roller bearings, that in such bearings adjacent balls or rollers are pressed one against another, with considerable force. The surfaces of the balls or rollers, roll in opposite directions, as shown in Fig. 5, and, therefore, with sliding friction. This is assumed to be a serious defect, by those who reason, that these surfaces contact under pressure. A cure often adopted, is the introduction of a smaller ball, between two larger ones. This method, however, is fallacious, as it is based on a failure to recognize an axiom in mechanics according to which a force whose direction is normal to the supporting surface, has no component in any other direction.

Correct Ball Bearing Mounting.

Ball bearings do not differ from other elements of mechanism, in that they must be used in conformity with their individual characteristics. A strict adherence to the following directions will result in a reliability far beyond that of any other form of journal:

(a) The proper size selection for the load must be made. Rated capacities are usually for steady loads and speeds. Variations from these conditions demand recognition by a suitable cutting down of the listed capacity.

(b) Bearings must be lubricated. The oft-repeated statement that ball bearings can be run without lubricant is pernicious.

(c) Bearings must be kept free of grit, moisture and acid. This prohibits the use of lubricants that contain or develop free acids. It is entirely practicable, by very simple means, to respond to b and c.

(d) The inner race must be firmly secured to the shaft. It is best to do so by a light drive fit, re-enforced by binding between a substantial shoulder and a nut.

(e) The outer race must be a slip fit in its seat.

(f) Thrust ought always to be taken up, whether in one or opposite directions, by the same bearing. That avoids all strains due to flexture of the shaft or of the housing, or due to temperature variation, and, while doing away with the considerable shop costs, inseparable from correct lengthwise dimensioning, avoids the danger of excessive end loads from forcible assembly consequent on an inaccurate lengthwise location of parts.

(g) Bearings should never be dismembered; or at least, never more than one at a time; that will avoid the danger of mixing balls from different bearings. Such balls from different bearings are apt to vary far more than is permissible for the individual bearing.

Fig. 4 will serve to show the arrangement of the ball bearings, and give an idea of a simple and useful locknut.

Particularly with machinery that is subject to vibration, it is necessary to lock firmly the nut that clamps the inner race. It is unsafe to rely on any form of a threaded lock; that also is likely to jar loose. Castellated nuts, etc., are unsightly and only permissible at the end of a shaft. The arrangement recommended consists of a split wire ring that is sprung into a groove turned circumferentially into the nut. A pin dropped into a hole drilled through the nut and partly into the shaft will be prevented from falling out by this guard ring. To permit of easily getting the pin out it is sometimes allowed to project and the ring is passed through a hole near the outer end of the pin. Not infrequently pin and ring are combined by bending the end of the ring over to act as the pin. The same arrangement is useful also when the nut is threaded on the outside to lock the outer race of a ball bearing, as here shown.

The ball bearing in its application to heavy work and serious engineering, is of recent development, for it is only in the past few years that material progress has been made. A great amount of work has already been done, testing materials, both chemically and physically, and there is still a wide field for research along this line.

Economy in Shop Supplies

The Attention of Superintendents and Foremen is Directed to Several Sources of Loss in the Factory, and their Remedy.

By George D. MacKinnon, B.A. Sc.

The object of the writer of this article is to draw the attention of proprietors and managers of manufacturing establishments to one phase of the business which is very frequently overlooked, either because it appears unimportant or because it is difficult to get time to look into it. I refer to the use of shop supplies such as oils, waste, belts, slushing compounds, boring and cutting compounds, emery wheels, coke, sand, coal, etc., and as it will be realized that in addition to other beneficial results, any economy in the matter of these supplies increases the net profits as well, it is something worth looking after. For instance, the economy in the use of coke in a foundry cupola, when that economy is produced through a study of the processes in the cupola, or through some arrangement whereby the hot and otherwise escaping gases are utilized to assist in the melting of the iron, generally better and hotter iron is the result, the castings are more easily machined, less power is required to drive the blower, less work for the men in charge, etc., the resulting economy is not only due to the saving in coke, but is the total of all the indirect benefits. This is not only true of coke, but of practically all other shop supplies. Take the case of emery wheels. An emery wheel specially selected for a certain kind of work cuts far faster, lasts longer and requires less time for toning up—and this latter item is often a large one—when the wheels are used in special grinding machines, such as the Norton plain grinder or the Sellers' universal tool grinder.

Belt Drive.

The matter of belts is sometimes given very little consideration, it being taken for granted that belts, must break occasionally and must be fixed, and it does not seem to enter into the minds of some that one special method of joining a belt may be better than another, or that another brand or quality of belt might give better satisfaction than the one in use. Neither is the cost per year of belts for a certain machine often figured up; while in a great many cases this expenditure for new belts and for time spent and lost in fixing them up when they break, would be almost entirely saved through some other system of driving.

The writer has in mind at the present time, one mill in a machine shop

for which the yearly cost in belts is upwards of $100, while the cost of the time lost, etc., in repairing these belts almost equals the first cost of the belts, or a total for one machine of from $150 to $200. How much better it might be for all concerned to do away with these troublesome belts and install another drive, the interest upon which investment would be only a fraction of the yearly cost of the belts.

Oil Consumption.

One of the large steel plants in the United States was using in connection with its machine shops something like 800 gallons of machine oil per month. The question of economy in the use of this oil had never entered the head of the superintendent, as he, like many others believed, since he had a good, general system in force in the shops, that this detail was being looked after as it should be. However, while speaking to the agent of the oil company during one of his periodic visits, the question of the quantity of oil used was brought forcibly to his attention by the agent asking him if he had ever attempted the regulation of the supply. The superintendent replied that he did not consider that the supply was very great, considering the number and size of the machines, and the amount of work turned out, but as he was one who believed that a dollar saved was a dollar earned, he instituted an investigation, the results of which were so gratifying that other investigations followed with equal success. The investigation of the oil supply was begun on an exceptionally heavy 12 ft. plainer. All the principal bearings were fitted with sight feed oil cups, which were regulated by the machine tender, and observations were made each day for a period of two weeks, records being kept of the quantities of oil issued to planer, number of drops per oil cup per minute, and actual time machine was in use. It was found that as much as four (4) quarts of machine oil were used some days, while one and one-half quarts sufficed on others—the average being about two and nine-tenths (2 9-10) quarts per day. With judicious use it was found that one and one-half (1½) quarts was ample—the planer being run double turn—and the supply from the tool room was consequently limited to this amount.

General observations were also made of the quantity used on each machine in the shops, with the result that a considerable saving was found possible. For example, some boring mills which were running almost constantly, were using from three to four quarts per day, while others used only one and one-half quarts. One large ingot lathe, which had probably six changes of work per day, used four quarts, while another doing exactly the same work, but a newer machine, used six quarts. It can be inferred that this was not an economical use of oil, and the quantities were reduced to one and one-half, and two quarts, respectively, on which quantities the machines continued to run satisfactorily. The oil supply for each of the more important machines was regulated and table No. 1 gives comparative results. This table shows the quantities of oil used during the four months preceding and the four following May 1st, when limits were put into effect. No data is at hand for the period previous to January, 1901, and 1903, is not included, because there had been in that year great increases in plant, while during the period given the amount of work done was practically constant from month to month. A saving of 27.22 per cent. is, of course, worth considering, amounting as it does in this case to practically $450 per year. All oil was issued from the tool rooms but there was no idea of limiting the supply to the detriment of a machine, and if the supply at any time fell short of the amount required, an additional quantity could be obtained on an order from the foreman—but, as a rule, these orders were very few.

A	JAN.	FEB.	MAR.	APR.	TOTAL	AVERAGE
1901	814	710	922	805	3251	812 ¾

" A - 1902 " A-1901 = 885 " = 27.22 "						
" B - 1902 " A-1901 = 652 " = 20.06 "						

Table No. 1.

Slushing Compounds.

Another supply used to quite a large extent in many shops is slushing compound. In many places this is a mixture of white lead and suet made by rendering the suet and mixing in the lead while hot, adding a quantity of machine oil to thin the mixture, if necessary. This makes a very good though very expensive compound. A much cheaper article may be made by mixing in suitable quantities, cylinder oil, asphaltum paint and Japan dryers. This may be made for about 70c per 1,000 sq. ft. slushed, against $2.60 for suet and white lead, and in the run of a year the saving is very considerable.

Emery Wheels.

As should be the case in connection with the use of almost all shop supplies, accurate records should be kept of all emery wheels, of the total time each wheel is in use, the number of pieces or tools ground—if on special work—the kind or hardness, etc., of articles ground and the grade, make and general character of the wheel, while in use. Some wheels require to be dressed much more frequently than others—some on account of being too soft, and some by reason of their glazing and refusing to cut. One instance occurs to the writer where 9-inch. dia. x ⅛-inch thick wheels, were being used by the dozen for nicking the cutting edges of heavy boring cutters. It occurred to mind that they must be of very poor quality, even though the men using them considered them o.k. A change was made, and instead of from 40 to 50 tools ground by each wheel, the number went up to 110 and 120. While with a wheel

¼-inch thick the number increased from 10 and 12 (much larger tools) to each wheel to 65 and 70, and this latter number with only about ¼-inch worn from the wheel.

A wheel ¾-inch thick, which lasted on an average one week, was replaced by one of another grade, which lasted five weeks. By some experimenting, the number of tools ground on a No. 1 Sellers' tool grinder was increased one-half by a change in the wheel, and as the wheels for these machines are very expensive, a considerable saving was effected. Other results might be mentioned, but these will show the advisability of looking into the matter of the emery wheel supply.

Cutting Compound.

In many places oils are used for bolt cutting, turret lathe work, boring, drilling, etc., while in almost all cases one of the many cutting compounds now on the market might be substituted, and a considerable saving thereby made.

A change was recently made in the construction of the fire places in a foundry core oven, with the result that at an outlay of less than $20, from $400 to $500 per year has been saved as a result of the decreased amount of coke necessary.

Most of the economies effected in a manufacturing establishment are due to the keeping of accurate records, and in the case of shop supplies, as in other cases, a competent manager is able to tell very quickly from a perusal of these records, whether or not the quantities used are too great, and may, consequently, take measures to regulate the consumption. Without such a record, however, he is not in nearly as good a position to judge, with the result that much is wasted, the cost of which, with the addition of the indirect benefits, would otherwise increase the net profits of the company.

Electric Power from Mouth of Coal Mine

The new power plant of the Maritime Coal & Railway Co., at Chignecto, Mines, N.S., is unique in many ways. Some years ago Thomas A. Edison, when in England, predicted that the ultimate solution of the problem of cheap power was the utilization of the waste products of the coal mine and the situation of the power house at the mouth of the mine, when the necessity of expensive transportation of coal over long distances would be eliminated.

This idea has been fully carried out by the Maritime Coal & Railway Co., and it is of great credit to Canada in general, and Nova Scotia in particular, that the first adoption of Mr. Edison's idea has taken place in the oldest Province of the fair Dominion.

In developing power, the first great saving is in the use of fuel which would otherwise go to waste. As there are no vertical shafts at the mines, the coal is hauled up a steep slope in cars, which are pulled by a cable. The cars hold fifteen hundred pounds each, and there are six cars to a train. When the cars reach the surface they continue on their journey up a slope to the top of the bank head. Here a complete system of tracks and switches places each car exactly where it is wanted. Its contents are automatically dumped into a series of screens and hoppers, where the material of commercial value is separated from the waste screenings or "culm." The good coal works its way to the railway cars waiting to receive it. The culm is dumped on an endless conveyer, which carries it to the power-house, 300 feet away. Here it is deposited in a huge bin above the boilers, which has a capacity of 85 tons. From this bin chutes, through which the coal is carried, lead to Jones' Underfeed Stokers, which automatically feed the fires. The boilers are four 200 horse-power return tubular, arranged in banks of two each. They supply steam at a pressure of 150 lbs., and the arrangement is such that any two can supply steam to the engine. A Cochrane open type feed water heater is provided, and the induced draft system, consisting of two blowers, complete with engines, supplied by the Canadian Buffalo Forge Co., has been installed. This does away with a high smoke stack, one only twenty-five feet high being used.

Water is supplied to the boilers by a pond made by the damming of a small stream. The pond is 1,000 feet away from the power house, and the water is conveyed by gravity to a pit underneath the boiler room, whence feed water and cooling water for the condenser is taken.

The power house is built of brick and is 75 by 50 feet, and is divided into the boiler and engine rooms. The engine room is 30 feet wide and runs parallel to the boiler room.

The engine is a 17-inch and 33-inch x 16-inch 750 h.p. Robb, Armstrong centre crank cross compound vertical condensing engine, of the English high-speed type, using the pressure oiling system, which carries oil to all bearings continuously at a pressure of 10 to 15 pounds. This is a new departure for Canadian engine builders, and has been successfully carried out by the Robb Engineering Co., Amherst, N.S., for the past year, a great many installations of this type of engine having been made throughout Canada by the company.

Directly connected to the engine is a 500 k.w. 11,000 volt three-phase alter-

Maritime Coal, Railway & Power Company, Chignecto, N.S.—Panoramic View.

nator, built by the Canadian Westinghouse Co., Hamilton, Ont. On the same shaft as the generator is the small direct current 125 volt exciter, for exciting the generator fields, making a very compact and substantial unit.

Power From the Mine.

Provision has been made for a future unit when the demand for power warrants its installation.

At the end of the engine room the switchboard is placed, which at present consists of a generator panel containing an 11,000 volt oil switch, with voltmeter, ammeters and wattmeters. There is also provided a synchronizing outfit to be used when the second unit is installed. The line is also fused with a set of high voltage fuse switches, and the whole equipment is protected by lightning arresters and choke coils of the standard type, manufactured by the Canadian Westinghouse Company.

The transmission line extends to Amherst, a distance of 6½ miles. Several long spans have been necessary in crossing the tidal rivers, varying from 400 to 700 feet. To cross these two poles were set at either end, guyed by steel ropes. The transmission wires are No. 4 B & S guage hard drawn copper wire supported on 15,000 volt glass insulators.

In general, the poles are 125 feet apart. Provision has been made for running a second line, as room for three more wires has been left on the cross arms.

At Amherst, a brick sub-station has been erected two storeys high. The upper portion is occupied by the three Westinghouse oil-cooled, self-contained transformers, which are used to reduce the voltage from 11,000 volts to 2,400 volts. Here also are located the fuses and lightning arresters. The secondary circuits are carried to the ground floor, where an oil switch is installed.

From the sub-station the power is distributed locally to the various consumers in Amherst and vicinity at a pressure of 2,400 volts.

To date, 400 horse power in motors has been installed, and it is expected that more will be in use in a short time. It is hoped that this will be the means of bringing many more industries to Amherst and vicinity.

Power From the Mine.

The largest consumers of power are the Robb Engineering Co. and the Rhodes, Curry Co., Limited, who have found that Central Station power is the most satisfactory solution of the power problem, and, when all charges for the isolated plant are fully accounted for, is cheaper and infinitely more satisfactory.

Power generated under such conditions cannot be affected by shortage of coal from the mine strikes or any other cause, as the refuse from the mine is sufficient to carry the power house over a very long-protracted strike when it would be impossible to ship coal to outside points.

So this company, in embarking on a project comparatively new to the world, and particularly new to the American continent, has, besides having ample cheap power for its own use, found an unlimited market for supplying power to distant centres. This provides a means of utilizing at a good profit what would otherwise be waste culm, and might occasion expense for removal.

The consulting engineer, in connection with the installation, was Julian C. Smith, C.E., general superintendent of the Shawinigan Water & Power Co., Montreal. The mechanical engineer was Mr. Philip A. Freeman, of Halifax, and to the wide experience of these men in power plant practice is largely due the success of this undertaking.

TAPER TURNING.

By J. H. R., Hamilton.

Here are a few rules which are very useful when turning tapers: Always have cutting edge of tool level with the centres of lathe or boring-mill table, otherwise there will be an error corresponding to the elevation or depression of the tool as shown in Fig. 1.

Tapers are either a cone or frustrum of a cone, and the only straight line that can be drawn on a cone is from

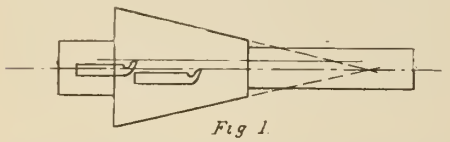

Fig 1.

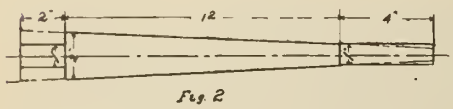

Fig 2

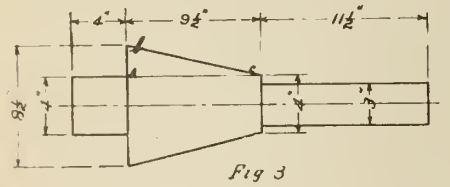

Fig 3

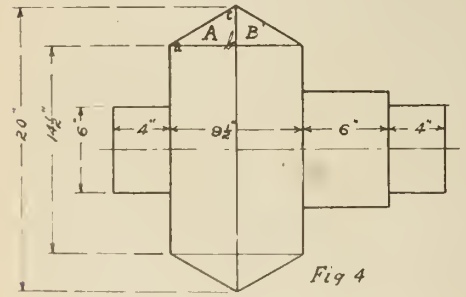

Fig 4

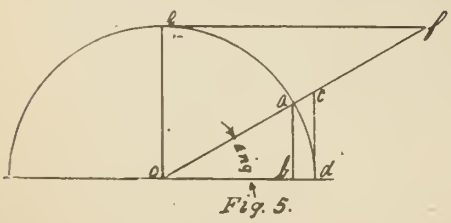

Fig. 5.

the apex to the base, therefore the cutting edge of tool must travel on this line.

If the taper is a certain amount per foot, the tail stock should be moved over one-half the taper per foot (where no taper attachment is used). Example: The taper is ¼ in. per foot; move tail stock over ⅛ in. per foot.

When taper does not run full length of work it must be calculated the same as though the taper was the whole length, as in Fig. 2.

Taper 1 in. in 12 in., therefore, in 18 in. would be 1½ in. taper.

Where taper is too quick for tail stock adjustment, the compound rest must be used. Sometimes the angle is known, at others it must be found.

In Fig. 5 the trigonometric functions are shown for the solution of triangles.

a o b is the angle.
a b is sine of angle.
o b is cosine of angle.
e d is tangent of angle.
e f is cotangent of angle.

$$\text{Rule 1—Sine} = \frac{\text{side opposite}}{\text{hypotenuse}}$$

$$\text{Rule 2—Cosine} = \frac{\text{side adjacent}}{\text{hypotenuse}}$$

$$\text{Rule 3—Tangent} = \frac{\text{side opposite}}{\text{side adjacent}}$$

In Fig. 3 angle b is required. Using Rule 3:

$$\text{Tangent of angle b} = \frac{9.5}{2.5} = 3.80000$$

Looking in table of tangents for number 3.80000, we find 3.80276 opposite angle 75° 16', which is the angle to place the compound rest.

In Fig. 4 angle c is required. Using Rule 3:

$$\text{Tangent of angle c} = \frac{4.75}{2.75} = 1.72727$$

Looking in table for number 1.72727, we find 1.72741 opposite angle 59° 56', or, say, 60°, which is the angle to place the compound rest.

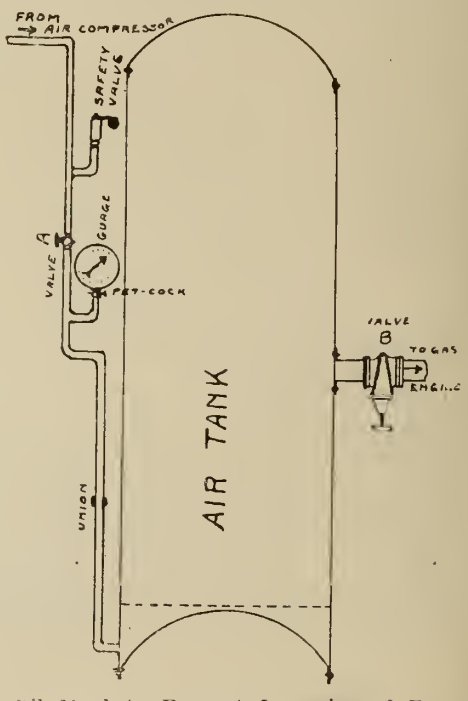
As triangles A and B are similar, move the rest to the same position right or left.

Table of sines, cosines, tangents and cotangents for even degrees, can be found in "Data Arranged in Handy Form" in the September issue of Canadian Machinery.

AIR TANK AND OPEN HEATER.

By R. Manly Orr.

Some time ago my firm added to their power plant a 50 horse power gas engine. Now an engine of this size is too large to be started by spinning round the fly wheels by hand, as is the practice with smaller machines, and, consequently, one of the accessories furnished with the engine was a steel air tank constructed for a pressure of over 200 pounds per square inch, and to be used for that special purpose. After installing the engine and connecting up the tank as shown in the accompanying cut, I found that with the two valves, A and B, closed, the pressure would go down considerably during the night, and, the pressure necessary to start the engine being 80 pounds, I found myself almost unable to start the engine on the remaining air pressure on several mornings. I found it impossible to keep the small ½-inch fittings between the tank



Oil Used to Prevent Lowering of Pressure.

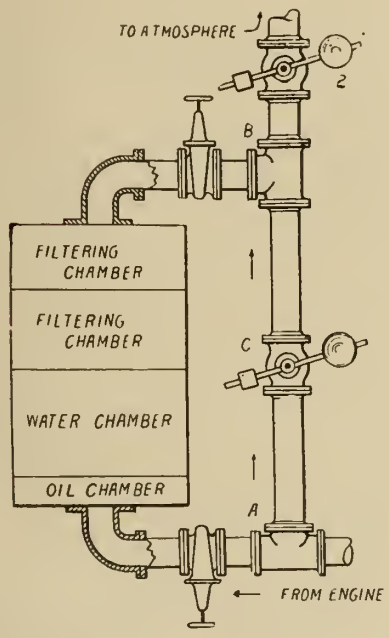
and valve, A, from leaking, under the 200 pounds air pressure, and I experienced considerable trouble with them until I thought of the following plan.

I put about one gallon of ordinary machine oil into the bottom of the tank, filling it up to the dotted line in the cut. Of course, when the air compressor had finished pumping up the pressure, and the valve, A, was shut, the oil backed up the pipe, filling it to the valve. Where the air would escape, the oil would not leak a drop. Now I can pump my tank up and let it stand

over two nights and a Sunday and the pressure gauge will not go back a single pound.

Open Heaters.

I would like also to add a point in connection with the piping up of an open heater, that experience has taught me. Many engineers are in charge of open heaters into which an overloaded engine exhausts; that is, an engine which, for more or less of the time, takes steam full stroke without cutting off. I have charge of such a heater and engine at present and well know what it means to have all the packing in the filtering chambers torn to pieces and piled up in a heap at one side, with the other side of the perforated floor of the chamber left bare. I have put weights on the packing and wired the top plates, but to no avail.



Arrangement of Piping and Valves.

When the exhaust valve opens a cylinderful of steam at boiler pressure bursts into the heater, and the result is somewhat similar to an explosion. The accompanying diagram gives an idea of my own which I believe is the best cure for this trouble; that is, except a bigger engine. The idea is to run with the valve, A, open and the valve, B, almost shut. B should be so nearly shut that a big rush of steam could not pass through the heater but will be by-passed through relief valve C. It will be easily seen that the easiest escape for the steam is through the heater, only one relief valve being on that route, thereby insuring a sufficient supply of steam for feed-water heating. The two relief valves can be weighted as the engineer sees fit. By closing A and B the heater can be cut out.

GANG-MILLING AS COMPARED WITH PLANING.

By C. S. Gingrich, M.E.

The illustration, Fig. 1, shows a machine part of very simple form and well adapted to setting many pieces at a time on the table of a planer for machining. It is the sort of a job on which a first-class planer hand would expect to make good time—in fact, these pieces have been planed repeatedly on a 36 in. x 36 in. planer, using two heads, running 55 feet per minute, finishing the two sides and the top, and at the same time, the slot, $\frac{5}{8}$ in. wide by $\frac{5}{8}$ in. deep, in 36 minutes each.

It was afterward decided to put this work on a miller. Fig. 2 shows how the job was set up. Two pieces were placed side by side. The machine was fitted with a gang of cutters, $8\frac{1}{4}$ in., $4\frac{1}{4}$ in., and 3 in. diameter, high speed steel. The cut was approximately 3-16 in. deep all over, and in addition there was also the

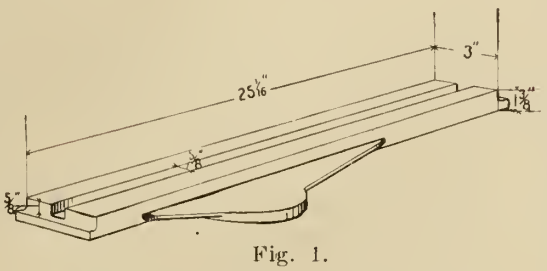


Fig. 1.

$\frac{5}{8}$ in. x $\frac{5}{8}$ in. slot to cut from the solid. The speed of the cutters was 38 r.p.m., and the feed .1 in. per turn of cutter, which resulted in a table travel 3.8 in. per minute. The total time for finishing the two pieces, including the chucking, was 18 minutes, or 9 minutes on each piece.

The miller was driven by a direct-connected motor, so that it worked up to its full efficiency at all times and removed the metal at the rate of nine cubic inches per minute.

The slot was required to be accurate as to width, and this necessitated the use of a special adjustable planer tool, which could be kept up to size after repeated grindings, and this, together with the regular tools required, brought the maintenance of the planer tools up to about the same expense as the maintenance of the milling cutters. It will be noted that the milling cutters worked at a moderate speed, at which they can be used for a long time without being sharpened.

UTILIZING THE EXHAUST HEAT OF THE GAS ENGINE.

Very few of the users of small gas engines realize the vast amount of heat that is carried away in the exhaust. The gases in the cylinder easily reach a temperature of 1,500 degrees Fahrenheit, and fully one-third of their heat is wasted. Steel manufacturers are now utilizing blast furnace gas, which formerly went to waste. Why is it not just as practical to use the hot exhaust gases from an engine cylinder?

The man who has a small pattern or machine shop, deriving his power from, say, a 20 horse power gas engine, can economize materially on his winter's fuel bills for heating. Usually he keeps three or four large open stoves going all the time, fairly eating up the coal, and only heating the shop in spots. If he will use his exhaust, he can obtain an even temperature all over the room,

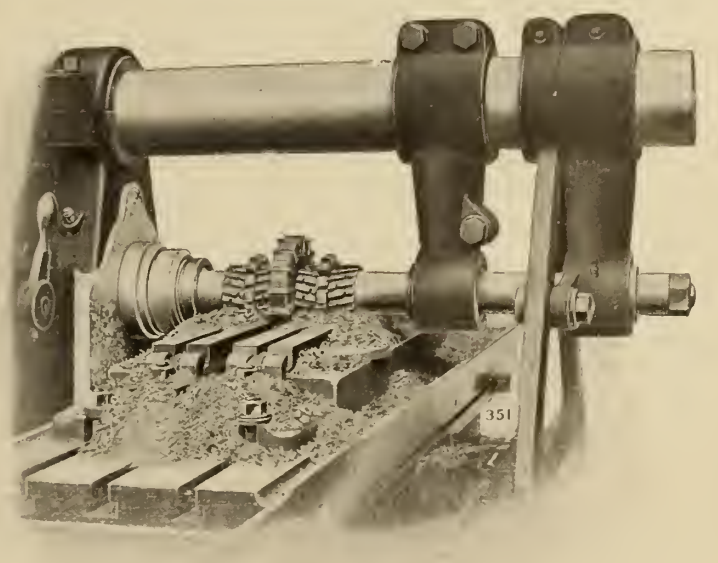

Fig. 2.

No. 4 Plain Cincinnati Miller removing 9 cubic inches of grey iron per minute.

and, at the same time, not burn any solid fuel.

If the shop is not too large and spread over too much area, it can be piped for hot water, with the circulating pipes running into a coil. This coil is placed within a metal drum, or box, properly protected with asbestos or some other heat insulator. If the engine exhaust is carried into this box or heater, it will heat up the water in the coils, thus starting through the pipes a circulation which will be constant. After the gases have become cooled in the heater, they can escape to the atmosphere through a waste pipe.

In a small pattern or woodworking shop, where the size of the engine is too small to be used for heating purposes, it can be utilized for a number of things, for example, the heating of glue. To accomplish this result, lead the exhaust into a larger pipe or water-tight box surrounded by the glue pot water. The hot gases will pass into this space, give up their heat to the water, and, finally, escape to the atmosphere through the outlet.

There is another advantage in thus using the waste heat. When the engine exhausts into a large box or receptacle, placed as near as possible to the engine, it acts as a muffler and silences the explosion without producing any back pressure in the cylinder.

The examples enumerated are but two of several uses to which the heat of this waste gas can be put by adapting apparatus to each local condition. It can even generate steam if a suitable boiler is attached. By utilizing this heat, men who previously were barred from using the gas engine on account of the necessity of having steam for their work, can install gas engines in their plants, and at the same time have steam for drying, seasoning, or any other use, without maintaining a separate boiler.—A. K. Reading, in American Machinist.

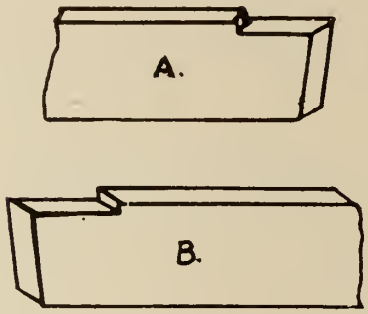
THE NECESSITY OF A PERFECT SYSTEM OF TOOL GRINDING.

By B. Pavey.

Few employers take notice of the great amount of time wasted by employes around the emery wheel; in the first place, waiting for their turn for the use of the wheel, and, secondly, the time taken in grinding tools.

Have you ever thought of the hours a three dollars a day man spends in grinding? Of course what I am speaking of is in regard to grinding tools for smaller lathes. A shop with which the writer is acquainted has a system as near perfection as it is possible to be obtained. Practically all work is turned with ½-in. square tools in holders, with a standard shape of tool. Each lathe hand is supplied with two, a right and a left, as shown in sketch. A round nose tool is supplied as well, if requested, but very few men are found to use them.

Steel is cut off in four-inch lengths by the smith in large quantities; a man



or boy grinds these in shape before they are hardened, so that after hardening they are merely touched up on the wheel with no danger of the temper deteriorating.

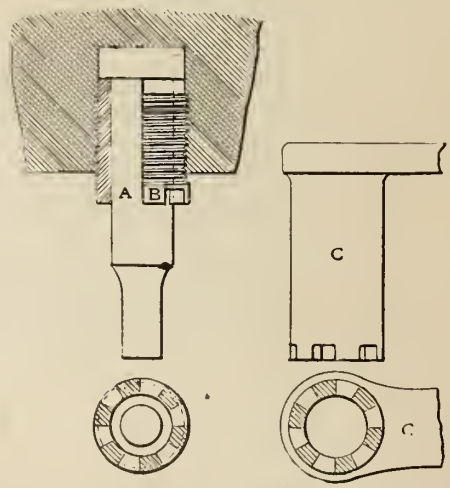
There are always tools in a finished condition kept in stock, so that a lathe hand, instead of grinding tools, takes his two tools to the toolroom window and is supplied with two fresh ones by a boy who looks after this part of the business.

By grinding the tool as shown in A and B it may also be used as a side finishing tool on almost all work and for roughing down there is not a better shaped tool.

The point of the tool will stand, being dead hard, and by setting the tool at an angle, a first-class finish is easily obtained.

SECURING PUNCHES IN THE PLATE.

In making multiple-punch tools, it is often necessary to locate the punches as close as possible to prevent handling the



Securing Punches in the Multiple Press.

work more than once. The design shown is one I have found to be most efficient on heavy work.

The punch A is held in place by the threaded sleeve B, which is tightened up with the special wrench C.

This arrangement also permits of any punch being removed or replaced without disturbing the others.—G. Riley, in American Machinist.

HOW JOHNNY SUCCEEDED IN GETTING AN INCREASE IN WAGES.

Johnny had been waiting for nearly a week to catch the boss when he was feeling good-natured to "strike him" for more pay. One morning the boss came around feeling in the best of spirits, and Johnny promptly took advantage of his opportunity. "Let's see, how many times have I given you a raise during the past year?"

"Twice," said Johnny.

"You are now receiving $2.50 per day; don't you think that is pretty good pay for a boy that has been 'out of his time' only a year?"

"No, sir; not when I notice that you pay green men $3.50 per day, and after they spoil the job you discharge them, and turn the job over to me to make. If a new man is worth $3.50 a day to spoil work, I surely must be worth $2.75 to satisfactorily complete the job."

"Those men you speak of hired out as first-class men; they lied to me and were promptly discharged, and I fail to see wherein their inefficiency has anything to do with your claim for more pay. What you need is more experience, and then more pay will be forthcoming."

Said Johny: "My argument is, that it is not experience that counts so much as one's ability, for in this particular case these men have certainly worked at the business longer than I, but were unable to do the class of work that I am doing. For instance," continued Johnny, "suppose that the very best tool-maker in the United States should come along here and hire out for $2.50 per day claiming that he had not been at the business very long, how long would he be obliged to work here to receive $3.50 per day? How often would you raise him—every six months, as you do me?"

"If he was worth more money I should promptly give it to him."

"Well, cutting out this 'experience' part of it and talking from the standpoint of a man's worth, don't you think that I am worth $2.75 per day?"

"Well, I guess you are, Johnny. I'll start you next week at $2.75."

S. E. F., in Machinery.

Gas Engine Pistons and Piston Rings

By Gordon A. Ronan.

Nothing, perhaps, about a gas or gasoline engine is of such vital importance to its successful operation as to have well made, well designed and properly fitting piston rings.

A gas engine may be well designed, and care taken to select only first-class materials for its manufacture, and yet if these essential features, viz., properly fitting piston and piston rings, are lost sight of, a loose, faulty compression will follow, with a resultant loss of efficiency in the power development of the engine room when it is completed and in operation. This failure to realize the importance of these moving parts in a gas or gasoline engine has caused many small manufacturers no end of trouble, when their products were assembled and ready for trial.

Attention should be drawn to the fact, also, that not a few makers believe, and adhere to, the practice of making a piston trunk, just a neat working fit for the cylinder bore, having the walls of the trunk parallel their entire length. Now, that this is wrong, will at once appear obvious, when we consider the element of "heat conditions" which enters into all internal combustion engines and which is so often lost sight of. Hence, heat plays an important part, and calls for consideration in the piston trunk design. The heat caused by the numerous internal explosions of the engine, gives rise to an excessive amount of heat in the compression end of all combustion engines, causing the piston to expand unequally at this end, and to overcome this a piston should always be machined slightly tapered. If this fact is not taken care of, the piston, if machined parallel, will expand unevenly and cause a tight and improper fit, which will prove most detrimental to any engine, causing undue friction, and is apt to lead to piston seizing and scouring of the cylinder walls. Too loose fitting pistons and piston rings have, on the other hand, their evil effect, allowing, as they do, the compression for that stroke to leak past both the trunk and the piston rings, and when the stroke is completed, only a partial compression remains.

Another feature of the piston so often neglected is one arising out of poorly designed pistons having a surplus weight of metal, when only the lightest possible trunk, consistent with the force acting upon it, should be used. Especially is this true in single cylinder gasoline engines, where the moving parts are all running at high rates of speed, and where unevenness in thickness or weight tends largely to produce undue vibration in the engine. In the accompanying illustrations, 1 and 2 represent types of piston trunks and rings used largely in gasoline engines, and show clearly the design of rings, allowing ample spring when placed upon trunk and inserted in cylinder.

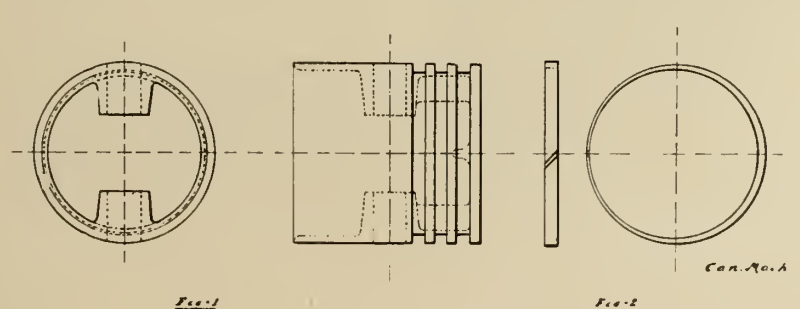


Fig. 1 Fig. 2

Finished Piston and Ring.

Mandril for Finishing Rings.

In Fig. 3 a cut is shown of a mandrel for accurately machining and leaving finished an eccentric ring suitable for all gas or gasoline engines. This mandrel is very simple in construction and operation, and, when carefully made, will be found invaluable to all gas engine makers.

The main portion of mandrel is of machine steel, turned on both ends, one end being threaded to take hexagon nut. This is done on the original centres, after which operation they are destroyed, and offset centres inserted, the required throw being given to allow for the taper piston ring. In this case shown the offset is 1-16 inch throw, the remaining parts of mandrel being a flange, a loose washer, and a hexagon nut, by means of which the eccentric ring may be held at the proper offset, while the finishing operation is going on.

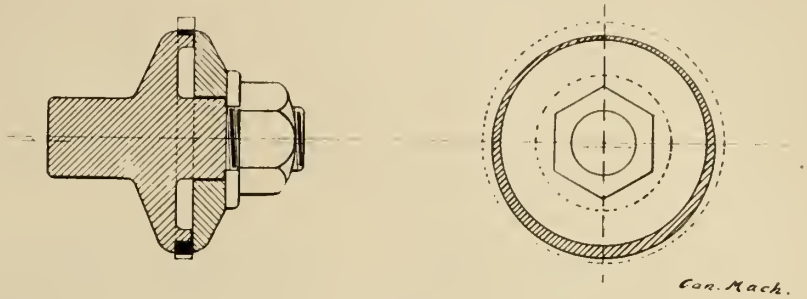

Fig. 3

Mandrel for Finishing Rings.

Machining the Piston.

In machining the piston trunk, care should be exercised to centre it by the core in casting, to insure a uniform thickness of the walls when the trunk is completed. Each piston should be machined on the inside wherever possible, to lighten and balance it equally.

The outside of piston trunk should be turned and finished smooth. While on the chuck, the three grooves are cut for the rings, after which the trunk should be slightly tapered. In this case the cylinder bore is 3.5-inch, and an allowance of one one-hundredth part of an inch is made, which will prove ample for the piston trunk expansion.

Turning and Finishing Rings.

The piston rings should be bolted to face plate of lathe by means of two lugs cast on one end of the casting. The inside of this casting should be bored to the required diameter to fit the bottom of groove, and a roughing cut taken on the outside. One edge should be carefully squared each time before rings are parted from casting and allowance made on each for refacing the opposite side, whether turned, ground or lapped.

All rings should be ground to a uniform thickness—1¼ inch—on either a regular ring grinder, or by means of lapping them, until two perfectly square and parallel walls are secured, when the rings may be split, ready for the mandrel.

By placing the rings upon the mandrel shown in Fig. 3, and holding the ring securely in an eccentric position over the shoulder left on mandrel, the whole is locked together by means of a hexagon nut, and a roughing and smooth cut leaves a perfect eccentric ring, ready for use in engine. This method has been thoroughly worked out in practice. By adopting this method, many troubles will be avoided, and satisfaction to all obtained.

Developments in Machinery

Metal Working **Wood Working** **Power and Transmission**

A NEW RADIAL DRILL.

The mechanical means for changing speeds and feeds are the features of most interest in the new radial drill here illustrated. There are 24 changes of spindle speed and eight changes of automatic feed to each spindle speed, any of which can be instantly obtained while the constant speed driving pulley is in motion. It is claimed that the changes are made without noise or shock, and being entirely gear driven, they are positive.

The two long levers shown in front of the speed box in the general view, Fig. 1, control four changes of speed, and to prevent accidental misuse of these handles they are interlocked by the small locking lever between them, so that it is possible to move only one lever at a time from its neutral position. A sectional view is given in Fig. 2 of the gear box, showing the gears,

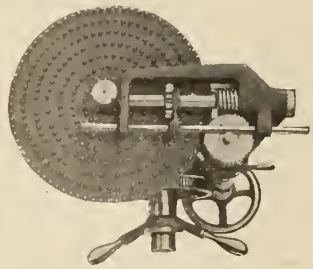

Fig. 3.—Top View of the Spindle Feeding Mechanism.

shafts and friction clutches. The latter are operated by the long levers referred to and cause the driving shaft to drive the intermediate shaft, which in turn drives the upper shaft in the speed box. The small lever on the right side of the speed box is used to bring the gears, which are shown in the sectional view, into mesh with the proper gears, D, E, and F, on the intermediate shaft, and three more changes of speed are obtained for each speed of the first driven shaft, making 12 changes of speed possible up to this point. This range is doubled by throwing the back gears in or out, which are located on top of the column, and are operated by the lever shown at the base of the column in Fig. 1. This lever is also used to bring the gear on the centre shaft in mesh with the gear on the elevating screw when required. When the elevating screw is reversed while lowering the arm, the gears D and G (Fig. 2) in the speed box are engaged without any intermediate gear, which causes the upper shaft in the speed box to reverse at an increased speed.

The column is in one piece, is bolted to the base and does not revolve. It is of heavy section throughout and is reinforced by four inside webs extending its entire length, making it capable of resisting the heavy strains imposed, particularly when the arm is at the top of the column and the spindle at the outer end of the arm. The arm is of hollow rectangular section, stiffened by an upper brace close to the face carrying the spindle head and a lower brace almost diagonally opposite, near the rear face. It will be appreciated that this provides admirably for resisting upward pressure of the spindle when drilling, by preventing twisting of the arm. A top cap resting on roller bearings supports the arm, and both may be swung completely around the column or instantly locked in any position by binder levers. The arm is lowered at almost three times the elevating speed by a screw having ball thrust bearings.

The spindle is of crucible steel and is ground. It is counterbalanced, has quick advance and return and provision for taking up wear. For tapping it is stopped, started and reversed by the long lever shown in front of the head, which operates two self-adjusting, noiseless friction clutches that are located on back of the head. At such times it is impossible to accidentally engage the automatic lever feed. This guards against breaking taps, as does also an adjustable gauge nut, which causes the spindle to slip when a tap reaches the bottom of a hole.

A positive automatic feed is provided for the drill spindle when high speed drills and reamers are in use, or a friction feed may be used when desirable.

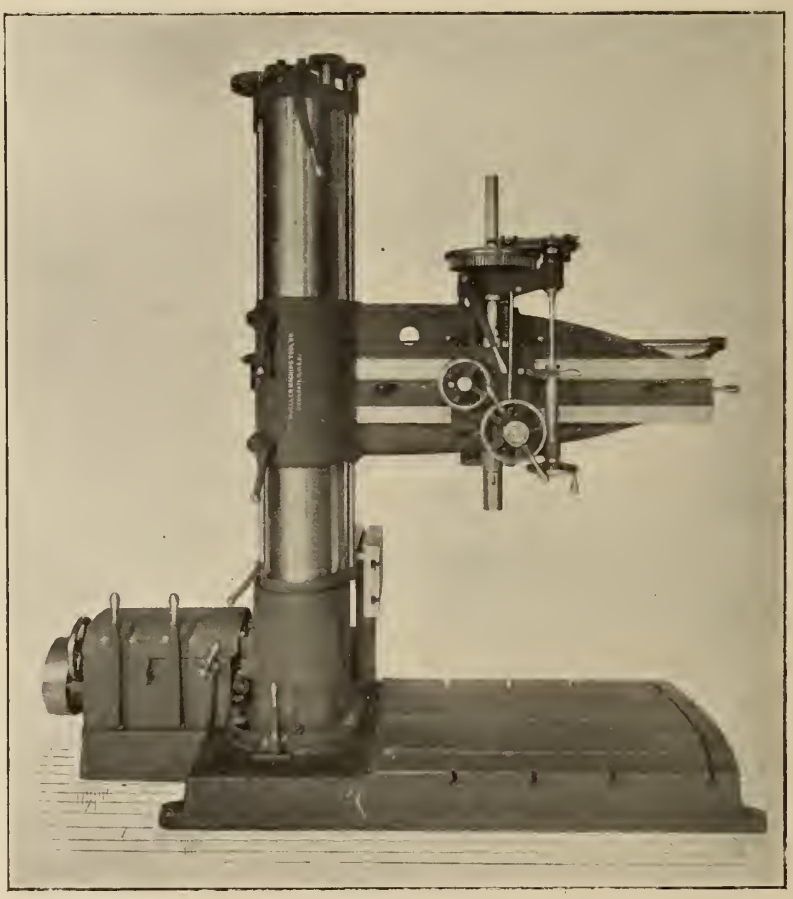

Fig. 1.—A new 4 ft. Radial Drill, built by the Mueller Machine Tool Co., Cincinnati, Ohio.

The change from one to the other is easily made by simply turning a nut. An ingenious mechanism, shown in Fig. 3, accomplishes the changing of feeds. A round plate having eight circles of steel pins in located above the spindle gear, and the pins engage with a steel

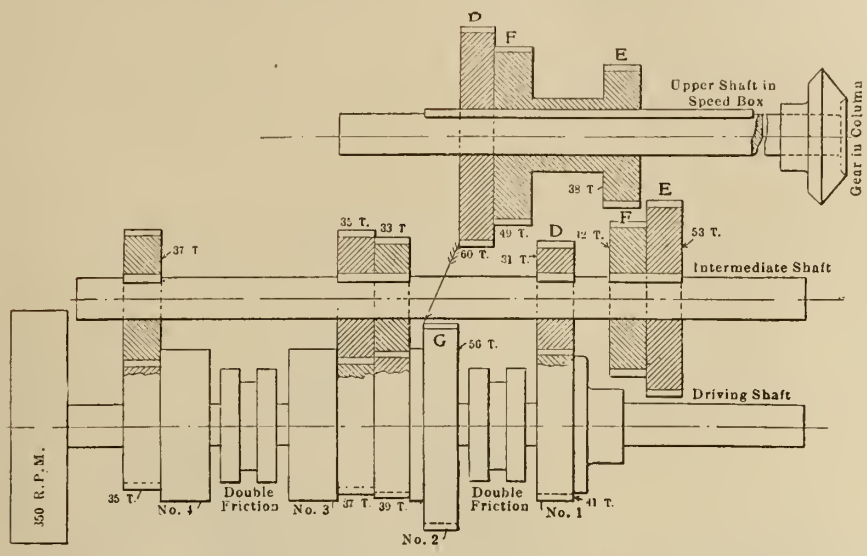

Fig. 2—Diagram of the Speed Box Gear ing in the New Mueller Radial Drill.

involute toothed pinion, feathered on a horizontal shaft, which carried a worm to transmit the feeding movement. The speed of this shaft is varied by means of a knob below the lower hand wheel. This knob is fastened to a rod which extends through the centre of the vertical feed shaft, and has teeth cut on its upper end to engage with a sliding rack and move the steel pinion into engagement with any desired circle of pins for fast or slow feed. These eight changes of feed may be quickly made while the drill is at work. The upper worm wheel has a split hub, and by means of a ring nut can be locked to the vertical feed shaft for positive feed, or slightly released if friction feed be required.

The automatic trip is provided with a safety stop, which prevents the feeding of the spindle after it reaches the limit of its travel. A graduated bar on the counterbalance weight is set to zero when the drill enters the work, and by means of several adjustable dogs on the bar the feed may be tripped as often as desired; these do not interfere with the spindle travel. The feed can also be tripped by a lever on the vertical feed rod.

Letters and numbers cast near the various levers on the machine indicate to the operator what levers to move and in what direction to move them, for proper speeds, which are given on a bronze plate fastened to the arm.

This machine is built by the Mueller Machine Tool Co., Cincinnati, Ohio.

AN OPEN-SIDE SHAPER.

The illustration shows a 15 in. x 60 in. open-side shaper, the smallest of which planes 15 in. in width. It is of the well known Richards type, with improvements, and for certain classes of work can be used to better advantage than either a pillar shaper, a traverse shaper, or a planer.

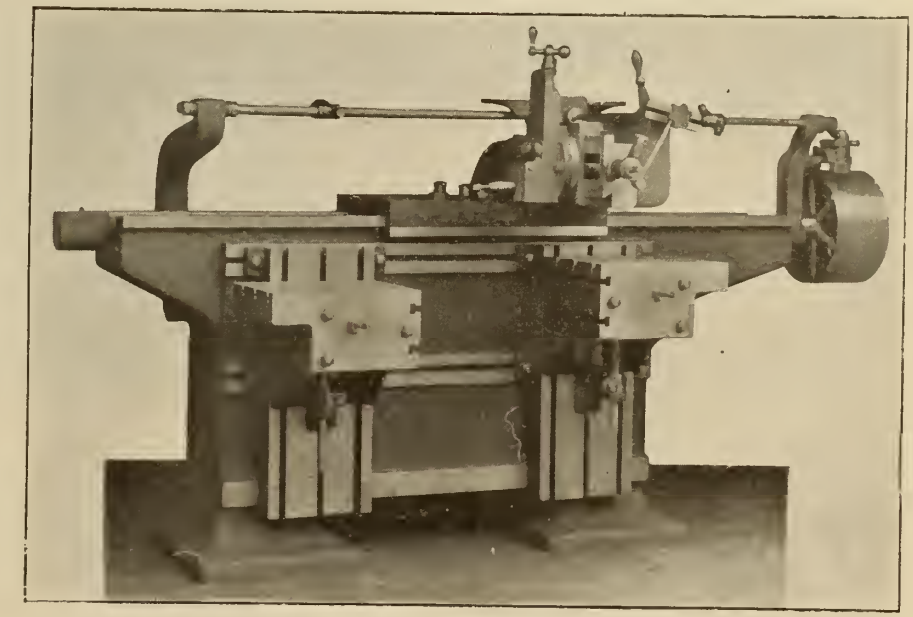
The machine is driven by a single screw and bronze nut, and without the intervention of any gears. The screw is $2\frac{1}{8}$ in. in diameter, and is made of .50 carbon steel. The saddle has a long and wide bearing on the column, with, however, a narrow and deep guiding surface to prevent binding, particularly when the tool is at the outer end of the rail, and is provided with a taper gib lengthwise, adjustable by screws at each end, affording uniform contact on both sides of the gib.

The cross feed is by power or by hand, is positive, and adjustable; the down feed is by hand. The reversing mechanism is of our design is new, and a decided improvement over existing methods. We depend on the turning of the shifting rod both for reversing and motion of the saddle, and for the automatic cross feed to the head, the rod being automatically turned by cams on the saddle coming in contact with dogs adjustable on the rod, or by hand from the saddle, if desired.

There are ball bearings for the shifting rod, as well as under the elevating screw to the table. There are taper gibs to the cross rail and to the head. The head has a down feed of $6\frac{1}{2}$ in., swivels, is graduated, and has a micrometer reading to .001 inches. The tables are raised and lowered by means of crank handles, or may be removed entirely and work bolted upon the aprons; or both tables and aprons may be removed entirely and work bolted against the face of the machine. Keyseating or shafting of any diameter may be done on the machine. All flat bearings are hand scraped to surface plates, and all steel slots cut from the solid. Ample means are made for oiling.

Length of stroke, 60 inches; width planed, 15 inches; maximum distance head to table, $23\frac{1}{4}$ inches; width of table, $15\frac{3}{4}$ inches; vertical adjustment of table, 19 inches; depth of table, 15 inches; down movement of tool slide, $6\frac{1}{2}$ inches.

This line of open-side shapers is built by the Cincinnati Shaper Co., Cincinnati, Ohio.

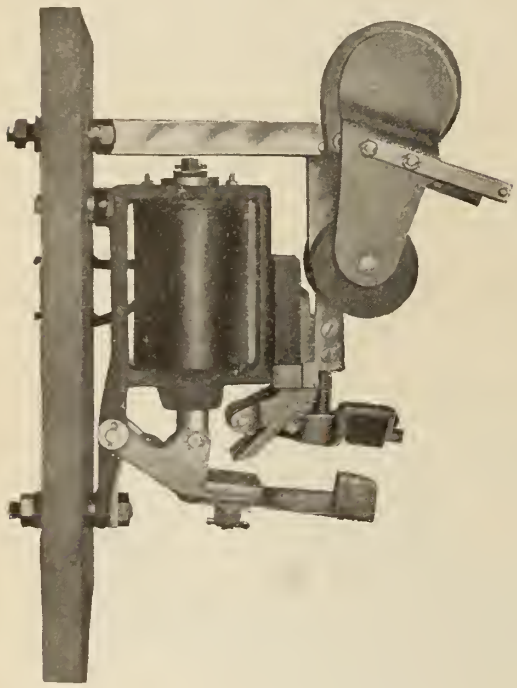


The Open-side Shaper, built by the Cincinnati Shaper Co., Cincinnati.

IMPROVED CONTACTOR.

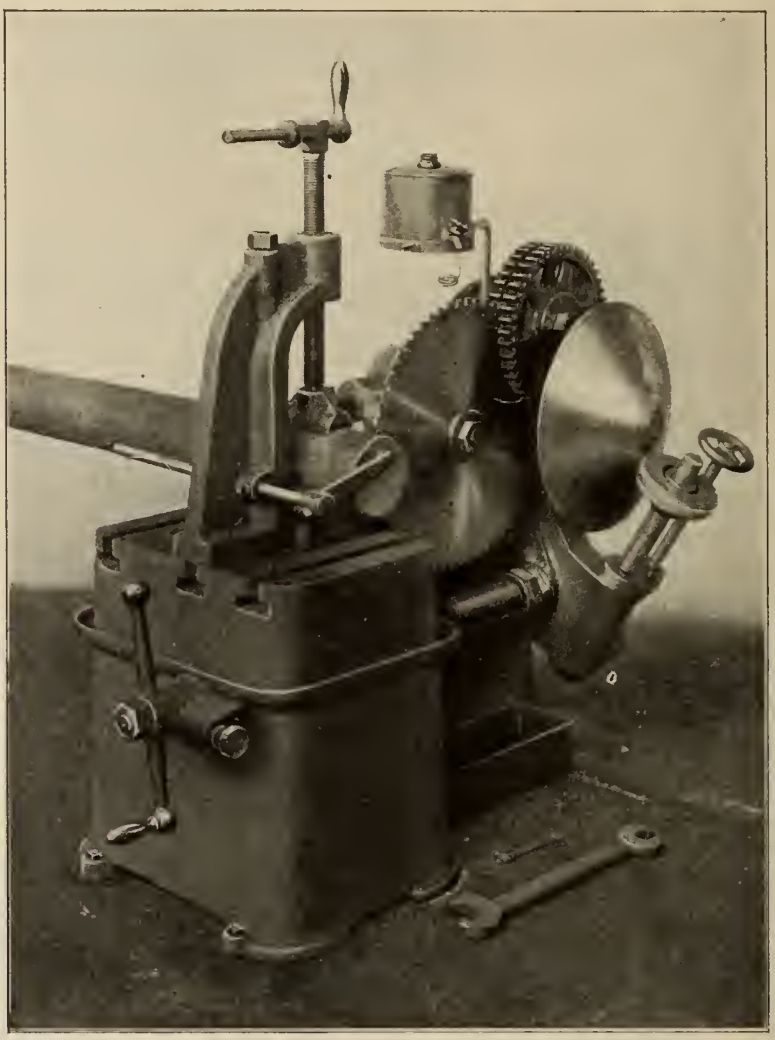
The Cutler-Hammer Mfg. Co., of Milwaukee, makers of electrical controlling devices, have recently placed on the market an improved type of contactor. These contactors are used for handling main line currents where the nature of service is severe. In such cases controlling sliding contacts cannot be relied upon to handle the main line current, and it is customary to employ a controlling panel consisting of a number of contactors, this panel in turn being controlled by a master controller designed to regulate the secondary current which energizes the solenoids of the contactors.

The improved contactor here illustrated is a compact and strongly constructed piece of apparatus, and is provided with an exceptionally powerful blow-out magnet. The main line circuit is closed by the solenoid raising a pivoted arm carrying a thick copper plate to a point where contact is made with a pair of stationary, laminated copper brushes. Arcing on this contact is prevented by providing an auxiliary copper and carbon contact in the field of a powerful blow-out magnet, which instantly extinguishes the arc incident to the breaking of the circuit. This auxiliary contact closes before the main contact is made and opens after the main contact is broken, thus effectually preventing any sparking on the main contact.



A noteworthy improvement is the pivoting of the blow-out shields, permitting these to be raised (as shown in illustration) so as to expose the auxiliary carbon and copper contact. In earlier types of contactors these shields were rigidly fastened in their normal position, completely covering the copper and carbon contacts, and rendering access to these difficult.

The present construction makes renewal of either contact, or of the coiled spring (visible just above the carbon contact) a matter of a few moments only. At a recent test at one of the largest Pittsburg steel mills a 220-volt circuit was opened and closed by a contactor of this type 88,000 times, before renewal of the copper and carbon contacts became necessary, and—on a test to determine time required for repairs—the old contacts were removed and new ones inserted in less than two minutes.



New Type of Metal Saw.

NEW TYPE METAL SAW.

The illustration herewith shown is of a new type of metal saw that the Quincy, Manchester, Sargent Co. have recently added to their line. The machine has been designed to meet a demand for a somewhat smaller machine than those they have been manufacturing in the past, and while embodying all the strength and wearing qualities of their regular line, the machine can be placed on the market at a figure that will be within the reach of many small shops that are not warranted in purchasing a larger and more expensive machine.

The method of driving the blade is rather novel and entirely different than any other method now in use. The blade, as on the Bryant type of machine, is driven from the periphery, but instead of the sprocket drive, steel rollers are used, these being hardened and ground and journaled in removable steel bushings, which are held securely in the double driving gear. By this method of drive a much larger diameter of the blade is available for cutting than can be obtained from a blade of the same size arbor driven, where about one-third of the diameter of the blade is necessarily occupied by the driving collars. It also has an advantage of economy in repairs.

The machine has a capacity for cutting rounds up to six inches in diameter; I-beams in a vertical position up to ten inches, at any angle up to 45

degrees. The feed is of the variable friction type, adjustable with the machine in motion, is powerful and continuous in its action throughout its entire range, and greatly superior to a ratchet feed; which necessarily is intermittent in its action.

When desired the machine will be furnished arranged for direct connected motor drive.

IMPROVED CARS DUE TO AMERICAN TOOLS.

From Paris correspondent of New York Herald.

Interviewed by a Herald correspondent on the question of American-made machinery in French automobile factories, the Marquis De Dion, head of the De Dion-Bouton Company, declared that if it had not been for the fact that American houses had been in a position to supply certain types of lathes, drilling machines, gear-cutting appliances and other intricate pieces of mechanism some years back, when the automobile movement began to expand, a popular vehicle could never have been considered by the makers at that time, while all classes of automobiles would necessarily have remained at extravagant prices.

"I'm not sure, to-day," continued the Marquis, "that we are still entirely dependent upon the American supply of machine tools to enable us to continue our production on the present lines.

"Great strides have been made by European constructors of such implements, and to-day we can purchase almost everything we want in Germany and England, and to some extent in France, at prices varying very slightly from those quoted by American firms. At the present time I am interested in a French company which constructs such implements and I have been led more or less to interest myself in the affair by reason of the difficulty, frequently experienced, of getting delivery of goods we want from American firms.

Deliveries Delayed.

"These firms have been so occupied that they have been in a position to afford to neglect orders from Europe, and I have met with cases where a year or eighteen months has passed before an order has been executed. At one time, not very long ago, we were entirely dependent upon the machines supplied by American constructors.

"All French automobile makers who wished to put their automobiles upon the market at a reasonable figure were compelled to consider what American firms had to offer. These machines are still used in my factory as well as in others, and to keep abreast with things we are compelled to turn to America every year for modern appliances and new, ingenious machines which enable us to produce higher grade automobiles at less cost.

"There are certain things about some of the American tools we have purchased which are not entirely satisfactory. Castings, as a rule, are not as resisting as they should be, and I doubt, in some cases, whether their machines turn out their work with such precision and accuracy as machines made in Europe."

Walking through the great works at Puteau the Marquis pointed out different types of American machines employed.

Many American Names.

"Here," he said, pointing to a row of implements at work on boring cylinders and finishing castings, "are machines supplied by Brown & Sharpe. On the other side are automatic machines by Pratt & Whitney. We also use stamping machines by the same firm.

"Those drilling machines there are by W. F. & John Barnes Co., while these metal planing machines come from the works of the Whitcomb Manufacturing Company.

"One of the most important things in automobile construction is gear-cutting. We have machines for this purpose supplied by various firms. Brown & Sharpe, the Gleason Tool Company, and Potter & Johnson have sent us most useful machines.

"For grinding up certain parts we have bought instruments made by the Norton Company, but it is difficult to mention all the American firms to which we are indebted for the various classes of work. We have tried almost all of them in turn.

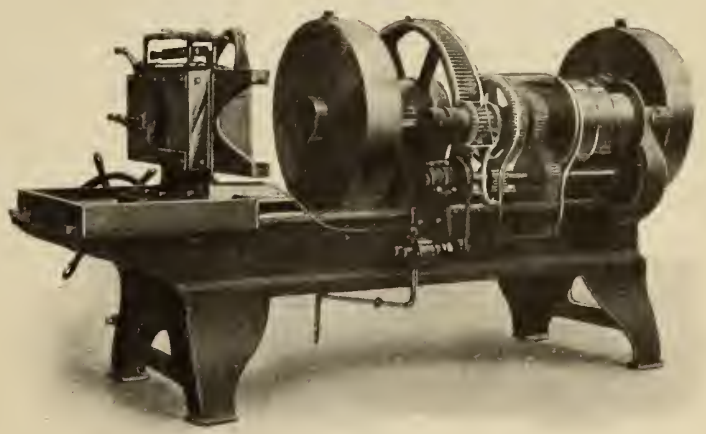
"You see, the majority of our machines are of American construction, but as we constantly are renewing it is impossible to say how long this will be the case. I think when the French company of which I spoke gets to work we shall be considerably less dependent upon American goods."

THE SCHANTZ POWER PIPE THREADING MACHINE.

A machine, just designed, and recently put on the market, which attracted a good deal of attention from the visitors to Machinery Hall at the recent Canadian National Exposition, was the Schantz Power Pipe-Threading Machine, manufactured by the S. E. Schantz Co., of Berlin. The accompanying illustration shows the special features of the machine, a description of which follows.

The No. 6 machine will thread pipe from 1½ to 6 inches. It is arranged for nine speeds, varying from 2½ to 40 possible rapidity. The head is fitted with two universal chucks, thus dividing the strain and providing additional clamping power. The back chuck steadies the pipe and assists the dies in their work.

The length between clutches is a noteworthy feature. The machine will accommodate a full length of 6-inch pipe without a third bearing.



Schantz Power Pipe Threading Machine

The cut-off attachment is fitted with self-centreing V-blocks, and with two cut-off tools, thus giving considerable advantage in speed. The tools operate very close to the blocks and thereby provide for steadiness.

The machine is fitted with a Borden r.p.m., and is specially designed to do the heaviest work with the greatest patent solid adjustable die head. All dies are adjustable and chasers are inserted.

The matter of lubrication is provided for by a Brown & Sharpe rotary oil pump, connected with the cut-off tools and the die with flexible steel hose.

The machine, as the photograph shows, is designed particularly for heavy work. Its great weight, 4,300 pounds, and the fact that all gearing is cut from solid metal, are factors in its reliability.

CANADIAN MACHINERY
and Manufacturing News

A monthly newspaper devoted to machinery and manufacturing interests, mechanical and electrical trades, the foundry, technical progress, construction and improvement, and to all users of power developed from steam, gas, electricity, compressed air and water in Canada.

EDISON'S DREAM REALIZED.

The throwing of a lever by Lieutenant-Governor Fraser, of Nova Scotia, causing power to be flashed along the lines from the mouth of the Chignecto Mines and the wheels to revolve in the factory of the Rhodes, Curry Manufacturing Co., Amherst, N.S., nine miles distant, was a great event, not only for Amherst and vicinity, but for all coal mining districts. Owners of coal mines throughout Canada and United States can now follow this example with confidence and generate their own power and supply cheap power to all factories in the vicinity of their mines. Amherst now has facilities which are bound to make it, in a few years, a great industrial centre. A word of commendation is due to the men who so bent their energies to the scheme that they now see the realization of their expectations of five years ago. It was a dream of the great inventor, Edison, that power would, in a few years, be generated at the mouth of the coal mines and be transmitted over wires to the various industries. It remained for Canada to develop Edison's suggestion, and now, in Amherst, N.S., it is an accomplished fact. The refuse or culm from the coal mine is the fuel used and the primary object of the whole system is economy. To use a refuse product, which was previously an expense, and transform it into power to run industries miles away, is a worthy achievement. Thomas A. Edison recognizes that this is a national success and sent the following message to H. J. Logan, Chairman Board of Trade Committee, Amherst, N.S.: "Permit me to congratulate your Board of Trade and Senator Mitchell on the inauguration of the first plant on the American continent for the generation of electricity at the mouth of a coal mine and the distribution of the same to distant commercial centres. It is a bold attempt and I never thought it would be first accomplished in Nova Scotia, where my father was born over one hundred years ago."

ABOUT OURSELVES.

It is with justifiable pride that we present to our readers and advertisers our October number. From the very first when Canadian Machinery was launched into a distinctly new field, the paper has been a success. From a sixty-four-page paper it grew to eighty pages, and the continued steady growth necessitated an addition of twenty-four pages this month, making one hundred and four pages inside the covers. With every issue during the year 1907 our paper has had increased business. Discriminating advertisers who know where to get results are placing their contracts with us, so that each month's business this year shows a distinct gain of about 40 per cent. over the corresponding month last year. This shows the confidence our patrons have in the selling powers of Canadian Machinery.

We have been alive to the needs of both advertisers and readers. Evidence of this fact can be gained by comparison of the different issues and a study of the progress shown. Advertisers are the backbone and mainstay of a publication, and it requires them to make it a success. To make a good medium for advertising, one that will bring results, a large subscription list is essential. This we have realized and we are building up a paper for the readers. With the increased advertising we have added a corresponding amount of reading matter. We spare no expense to get what the mechanical public want, and give it to them, and we are continually on the lookout for good, live, reliable articles. Our editorial matter is of the best and every issue has a fund of good information and ideas for manufacturers, superintendents, foremen and mechanics. As a result, subscriptions have come in from all over Canada and our representatives in the different provinces are meeting with excellent results.

Your suggestions and criticisms will aid us materially to reach the end towards which we are aiming, to give the readers matter best fitted for their needs and thus to build up a good advertising medium, one that will be of credit not to ourselves only, but to the profession and business that Canadian Machinery is endeavoring to assist. We trust our patrons and readers will do their share in helping this along.

Quebec Bridge Disaster

The news of the collapse of the Quebec bridge on August 29th, with the loss of over seventy lives, came as a shock to the whole engineering world. Engineers from all over the globe have watched with interest the progress of this great undertaking. This structure was expected to be the finest in the world and engineers of high standing and wide experience were employed in the designing of the bridge and the carrying on of the work. The designs were by the Phoenix Bridge Co.'s designing engineer, Peter L. Salapka, and the Phoenix Bridge Company had the contract of erecting the superstructure. The design and workmanship were, so far as yet apparent, of a high order. The erection methods were carefully thought out and the work had reached the fourth panel from the south end, or within two panels from the centre of the suspended span, when the blow fell. A large traveler weighing 1,000 tons stood at the end of the cantilever span. It had been dismantled to about one-third of its weight, so that the weight here was considerably reduced, but in the immediate vicinity was a small crane weighing about 200 tons, and on the end of the suspended span was piled an enormous quantity of structural steel. The accident occurred just as a locomotive with two cars of chord sections moved out on the erected portion. The trainload was not an unusually heavy one and it was the unexpected that happened when the structure went down, carrying with it over seventy workmen.

Dimensions of the Bridge.

This bridge is intended to be the longest single span cantilever bridge in the world, the length of the centre span being 1,800 feet, and the total length between abutments is 3,220 feet. It consists of two deck truss approach spans, each 210 feet long; two anchor arms, each 500 feet; two cantilever arms, each 562½ feet, and one suspended span 675 feet long. This will be the longest single truss span ever built. For a width of 1,200 feet there is a clear headway at high tide of 150 feet, to allow free passage of vessels. The weight of the heaviest single piece of steel for the bridge is 100 tons, and the total weight is 38,500 tons. The length of the longest single section is 105 feet. The eyebars are the largest yet used, with a maximum of 56 on one pin. The diameter of the pins is from 9 to 24 inches and up to 10 feet in length. The total number of field rivets to drive is about 550,000. The bridge will have a total width of 82 feet, including the cantilever sidewalks. It is designed to carry two railroad tracks, two highways, two electric car tracks, and two foot walks on a single deck.

The main piers were of concrete, faced with granite and sunk by pneumatic caissons, 150 x 49 feet and 25 feet high. The tops of the piers measure 133 x 30 feet and they contain 35,000 cubic yards of masonry. The anchor piers are of concrete, faced with granite, and are 30 x 111 feet at the base, and 56 feet high, from the bottom to the anchorage. They are 24 x 105 feet at the coping and contain 14,400 cubic yards of masonry. The abutments are of concrete, faced with granite, and are 80 feet wide, 40 feet deep, and contain 4,000 cubic yards of masonry.

The work of constructing the superstructure was under the direction of Theodore Cooper, consulting engineer, of New York, and was progressing rapidly. On account of the severe climate, the work was carried on between April and November and the best possible use was made of the time. On account of this rushing, the work of construction, it is thought that perhaps all of the rivets were not placed in position as the work progressed, but as yet the commission has found no evidence to justify them in this belief. There was no loud report at the time of the disaster, but the bridge sank with a grinding sound, followed by the snapping of some of the tie rods. The fall of the bridge appears to have been due to a failure of the compression members, rather than in the tension members.

A Convincing Argument to Advertisers

We reproduce below one of many similar letters received every month by our subscription department:

Canadian Pacific Railway Co.,
Office of Third Vice-President.

Montreal, Sept. 10, '07.

Canadian Machinery and Mnfg News,
Toronto, Ont.

Dear Sirs,– Commencing with the next issue, please have copy of Canadian Machinery sent to Mr. H. Osborne, Superintendent of Angus Locomotive Shops, Montreal.

Yours truly,
I. G. OGDEN,
Third Vice-Pres.

The Government Commission.

The Canadian Government has appointed a commission, consisting of Henry Holgate, consulting engineer, Montreal; Prof. J. G. Kerry, McGill University, and Prof. J. T. Galbraith, of Toronto University, to make a thorough investigation into the cause of the disaster. The commission is acting in harmony with the engineers of the bridge and it is of the utmost importance that these men come to some definite conclusion in order that public confidence may be restored in the scheme. Failing this, the question of restoring the bridge will be viewed with apprehension both by the public and the bridge engineer. The government realizes this and through the commission is trying to fix the cause of the disaster

The Latest Developments.

As the work of the commission goes on new facts are brought to light. Daniel B. Haley, of Sarnia, gave his testimony that he had seen several panels bent while standing on the third panel of chord nine. He also noticed the lacing was bent in chords eight and nine. The splice of the chords, he said, had not been properly riveted, and this matter was reported to the foremen. Conflicting testimony has been given in regard to one of the bridge plates. The workmen testify that there was a crack in one of these from 18 to 20 inches long and three-quarters of an inch wide. The deflected chord led to the sending of a message to Phoenixville and Mr. Cooper's asking them to look into this matter. Owing to the operators' strike, messages were delayed. Mr. Yenser, the head foreman in charge of the work, wrote, asking for a reply by telegraph, to say whether or not he should continue work. He was called on the long distance telephone and asked further about the matter. He said as there appeared to be no immediate danger, he was proceeding with the work.

It will in all probability take some time for the commission to locate the trouble. In any case, there will necessarily be a delay in the resumption of the work of erecting the bridge. The Phoenix Bridge Company wish to complete the work, provided the Canadian Government does not object, and at least two years will be necessary to reach the stage of completion of the bridge at the time of the accident.

PLANING MILL BURNED.

The Kennedy & Davis Milling Co., of Lindsay, whose planing mills and stave factory was entirely destroyed by fire on June 2, are rebuilding. They will install all new machinery, with the exception of the boiler and one large planer, which were but slightly damaged. They are in the market for cars, for the purpose of conveying the staves into the dry kiln.

Foundry Practice

MODERN IDEAS FOR FOUNDRYMEN

Moulding Cast Steel Lead Bowls

By H. J. McCaslin.

When a lead bowl reaches such proportions as the one illustrated, the molds are usually swept up, this being accomplished by attaching to and revolving about a spindle, as shown in Fig. 2—a sweep so arranged that the striking edge contains the outer and inner outline of the bowl to be cast.

While sweeping up a mold for an object of this form is of a very simple nature, it nevertheless may embody some points of interest for the young patternmaker or molder.

Beginning the work a full-size radial section layout (as shown to the right of the centre line, Fig. 1) is very essential, this layout being required in getting out the sweeps. The sweep may be constructed somewhat after the manner shown in Fig. 2, being secured to the spindle with collar and sleeves. Shown in greater detail, to the right of this illustration is a cross section of sweep on the line, BB, showing the metal thickness strip, A, which is detachable, being secured to the sweep proper with screws.

There is a difference of opinion existing between molders as to the most practieal manner of using the strip, A Some prefer to sweep up the outer form of the objeet to be east remove strip A, and then sweep upon this surfaee a thiekness of sand equivalent to the metal thickness. This thickness of sand is subsequently removed, following the ramming up of the cope. Others prefer to sweep up the inner surface of the object, ram up the cope and lift it off, detach strip A, and strike off the metal thickness. The latter method is the one preferred by the writer and the one that will be discussed in this article.

Fig. 2 illustrates a cross section of the mold at two stages of completion. At the right of the centre line is shown a cross seetion of mold during the operation of sweeping up the exterior form of the object. It is upon this surface the cope is rammed up and lifted off in the usual way. To the left of the centre line is shown the second operation of sweeping, at which time a thickness of sand equivalent to the metal thiekness is removed. Operations are started upon the mold by digging a hole in the foundry floor, of ample depth and diameter, and the firm setting and plumbing of the socket and spindle. Next, the sweep, with strip A removed, is attached to the spindle as shown, being adjusted to the required height by the eollar.

Heap sand is now firmly rammed in and struek off to conform to the sweep —as shown to the right of centre line, Form 2—as the completion of this operation, the parting to receive the cope flask is struck off, this being accomplished with the aid of a straight edge, and that portion of the parting formed by the sweep. The sweep and spindle being removed, the hole left vacant by spindle is filled with waste or other material, and a plate placed over it to prevent any sand from running or falling below. Parting sand or paper (paper preferred) is now applied over the entire surface and work upon the cope is begun. To facilitate the securing and lifting out of this body of sand forming the upper surface of the mold, a lifting iron is generally introduced near the bottom, as shown in position, Fig. 3. Extending up from the lifting iron are four bolts, whieh are used in seeuring this portion of the eope to the flask. Supported upon blocks, their depressions being filled up during the finishing of mold ; the lifting iron is placed in position. Siliea sand of about 1 ineh in thickness is now applied over that portion of the surface which eomes in contaet with the metal. Heap sand, well secured with rods, is then firmly rammed in to the height of the parting line. Next the flask is placed in position and staked ; the runner stiek and the riser head are arranged, followed by the firm ramming up of the flask, as shown to the right, Fig. 3. Before lifting off and

Fig. I

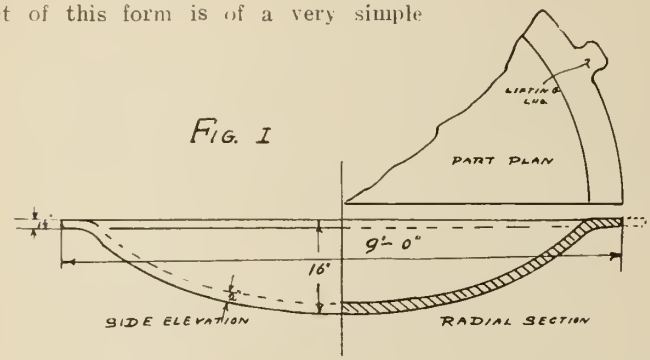

Fig. II

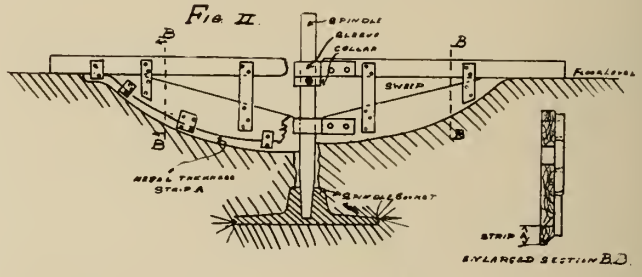

Fig. III

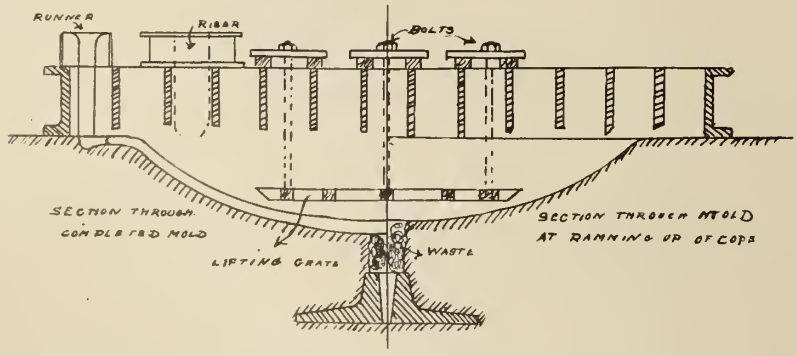

blocking up the cope, the two parts of this portion of the mold are securely bolted together, as previously mentioned. Operations upon the drag portion of mold are resumed by the roughing out with a shovel ample space to allow for a thickness of silica sand, and placing back in position the spindle and sweep with strip, A, attached. Silica sand is next applied, firmly rammed down and struck off to conform to the sweep, as shown to the left of Fig. 2.

With the removing of the spindle and sweep, the bedding in of the four lifting lugs, (the pattern being shown in greater detail to the right of Fig. 2) is proceeded with, this being accomplished by dividing the outer circumference into four equal parts, and the bedding in of the pattern at these points.

Finishing a mold for steel castings differs from that of iron, as nails are inserted over such surfaces of mold where scabbing must be prevented as far as possible. In this instance, the cope mold requires nailing. A silica wash is also applied over the surface of mold, and the mold is thoroughly dried by a coke fire or a gas burning arrangement. All that now remains is to blow out the mold, try the cope on to ascertain if the metal thickness is correct, this being accomplished with balls of clay set at several points in the mold. If everything is found all right, the cope is returned to place and ample weight applied to prevent raising when being poured.

An Improvement in Cupola Tuyeres

Cupola melting is one of the things in foundry practice that has not received the careful and scientific attention that it should have had in the past, and in many cases the cupola is considered fool-proof and expected to run itself. Foundry owners frequently wonder why they are having trouble with their iron, when, if they only knew it, the troubles are resulting in improper cupola work, due largely to the improper cupola design or construction.

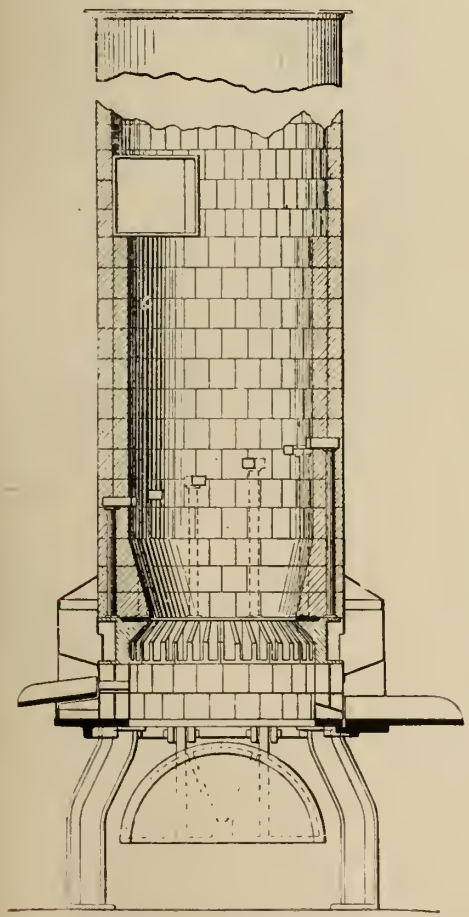

Fig. 1.—Vertical Section of a Cupola Equipped with the Knoeppel Tuyere.

Mr. J. C. Knoeppel, of 577 E. Ferry St., Buffalo, N.Y., has had more than twenty years' experience as a foundry manager, and given a very large amount of attention to melting problems. He has devised a tuyere system for which patents are now pending in the United States and Canada

The fundamental principle of good cupola work is to introduce the required amount of oxygen with as little disturbance as possible, and in such a manner as to give an equal temperature at all points around the circumference of the cupola; in other words, to avoid cold spots. To accomplish this, the blast must be uniformly distributed, and the tuyere area must be large. If a cupola lining is allowed to take its own course and assume the form which it naturally would where the cupola is normally slagged, it will be found that the lining will build out slightly above the tuyere and form a bosh above. Recognizing these facts and also recognizing the fact that large openings were necessary to deliver the air at the lowest possible pressure so as to avoid irregularity, Mr. Knoeppel has arranged his tuyeres as shown in the accompanying photograph. The castings composing the tuyeres form a continuous belt about the cupola, and in large cupolas the upper and lower portion of the tuyeres are composed of separate castings, while in the smaller ones they are all one casting.

The line drawing, Fig. 1, represents a vertical section through the cupola Fig 2 represents one of the tuyeres, which is provided with a safety notch in the centre, so that when the iron rises to this point it will flow through the depression in the centre and escape through a soft metal plate, thus warning the melter before the iron flows into the tuyeres proper.

Fig. 3 shows one of the key tuyeres. In these the upper flange overhangs the other or adjacent tuyeres, while the lower portion is made with parallel sides so that it can be drawn in to the centre of the cupola, thus releasing the

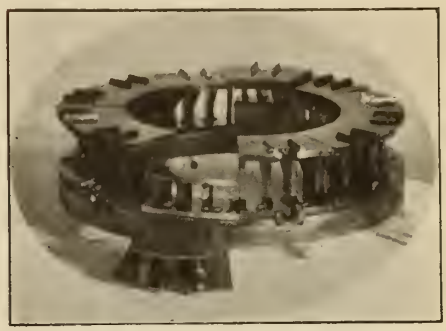

Fig. 2.—Knoeppel Tuyeres with one of the Tuyere Keys Removed.

other tuyere blocks. The tuyere blocks above the spout and above the slag hole usually have their lower tier of openings stopped with brick, so as to avoid any liability of chilling the outflowing slag or metal.

One of the most important points in

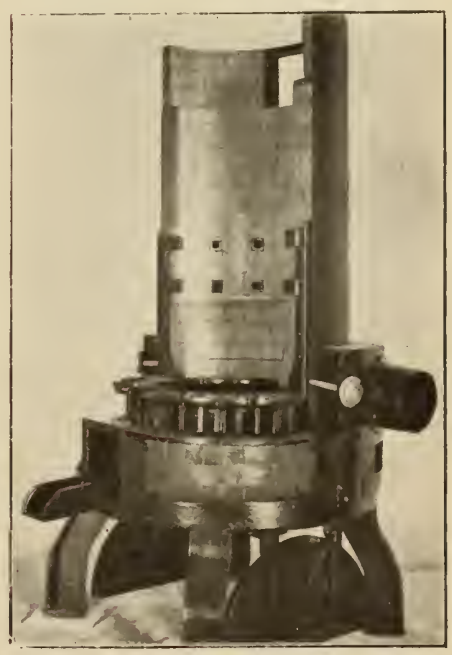

Fig. 3.—Section of Cupola Showing Tuyeres and Vertical Air Pipes.

connection with this form of tuyere, however, is the fact that it may be said to have two independent wind belts which will give the air a chance to equalize in pressure both inside and outside of the shell, thus insuring equal pressure at every tuyere opening. The

outside wind belt is a metal casing, as in the better style of cupola mountings, while the inside belt is formed by cutting back the vertical partitions of the tuyere blocks at the side next the cupola shell, as shown in detail in Figs. 2 and 3 and also in Fig. 1. A series of openings through the shell admit air to the back of the tuyere blocks, and this air then flows about through the inside air space. By making the tuyere area ample, the air flows at a relatively slow velocity and has opportunity to lag or rest in the tuyeres for a short space of time, thus enabling it to take

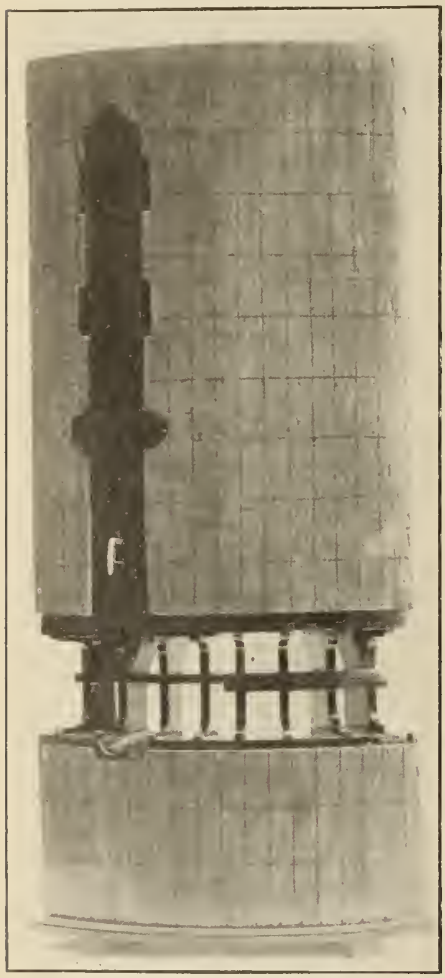

Fig. 4.—Cupola Lining with Shell Removed, Showing Vertical Pipe and Inside Wind Belt.

up some heat and to enter in the best possible condition for rapid combustion.

One important point to be observed in connection with the overhanging upper edge of the tuyere blocks is that this form effectually prevents the slag or metal in its downward course from flowing into the tuyeres and blocking them. It also prevents coke from sliding into and closing the tuyeres, thus insuring an ample opening at all times during the heat.

In the usual cupola construction, the lining is carried up vertically for a short distance above the tuyere blocks and then caused to flare out, forming the bosh. The brick lining is, of course, supported by angle irons riveted to the shell, as usual, so that the tuyeres can be removed if necessity should require any change in their arrangement.

One of the features covered in Mr. Knoeppel's patent is the provision for the introduction of air above the melting point, the object being to utilize to the fullest possible extent the heat contained in the gases. These openings are arranged by providing notches in the top of the tuyere blocks, which connect with vertical pipes next the shell on the inside of the cupola. These are provided with nozzles leading through the lining. In Fig. 3 there is shown a section of the vertical pipe taken through one of the nozzles. The nozzles are secured to the pipes with dovetail joints, so that they can be easily replaced. In operation during melting a small amount of air is admitted through these vertical pipes and is supposed to combine with the carbonic oxide gas, burning it to carbon acid. The heat thus set free will be to a considerable extent absorbed by the material as it settles toward the melting point, thus preparing the metal for rapid melting. These vertical pipes can be closed with dampers or valves which can be used to adjust the amount of air admitted above the melting point.

At the close of the heat the dampers in the vertical pipes can be opened wide and a volume of air allowed to pass up through the pipes so as to cool the lining.

In the case of very small cupolas, the amount that the tuyeres overhang on the inside would be reduced, and, possibly, in some cases, this overhanging would be entirely dispensed with and flush, or vertical tuyeres used. In such cases, Mr. Knoeppel provides cast iron plates which can be placed on top of the tuyeres so as to form an overhang of from one to two inches, thus providing for a small amount of boshing.

Fig. A is an outside view of the cupola with the shell removed, showing cupola lining. It shows the vertical pipe and gives a good idea of the tuyere blocks arrangement.

In Fig. 5 we have a sectional view on a larger scale, showing the tuyeres and the inside wind chamber.

The principal advantages of this tuyere system may be summed up as follows:

First, and most important, the introduction of a very large amount of air at a low pressure, thus insuring a low melting point and uniform conditions in the cupola.

Second, by the use of the overhanging upper portion of the tuyeres, the liability to the stoppage of tuyeres during the operation of the cupola is very greatly reduced, thus enabling much longer heats to be taken from the cupola.

Third, the inside wind belt provides an opportunity for thorough equalization of the blast pressure, thus insuring equal melting at all points around the circumference of the cupola, which is a condition that cannot be fully attained when the tuyeres are not continuous, and are supplied only with an upper wind belt.

Fourth, the form of the tuyeres, together with the use of the safety tuyeres, reduces to a minimum the liability of stoppage caused by metal rising into the tuyeres.

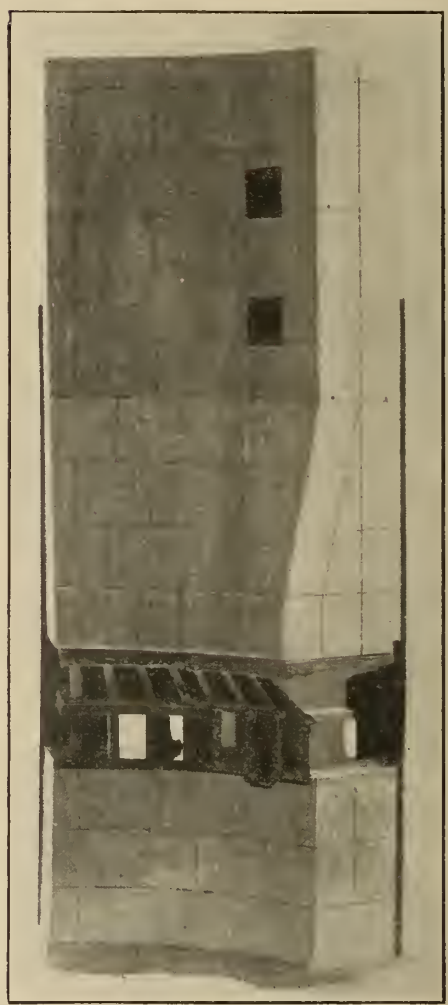

Fig. 5.—Section of Cupola Lining Showing Tuyere Blocks and Inside Wind Belt.

Fifth, the vertical pipes with the supplementary openings into the cupola enable the operator to control the conditions above the melting point as he may see fit.

Sixth. The fact that the tuyeres project from two to sixteen inches, delivers the air much nearer the centre of the cupola than in cases where the tuyeres are flush with the lining.

NICKEL IN CAST IRON.*

By James F. Webb, Elkhart, Ind.

In reporting on the tests authorized by this association last year, I beg to submit the following results: I made twenty test bars, ten with the nickel added and ten without, all from the same ladle holding 1,400 pounds, and of good hot iron. Nickel thermit was put into the bottom of the hand ladles, the aim being to get varying proportions of nickel into the metal and then to note results of the tests.

The determinations were made by H. E. Smith, of the Lake Shore railroad, and are presented herewith:

TABLE I.

Physical Tests.

Cast Iron Test Pieces from Elkhart, Ind.

Mark	Diam. inches.	Cross breaking weight.	Deflection.	Modulus of rupture.
1 N	1.25	3,000	0.11	46,870
1 N	1.24	2,970	0.09	47,520
2 N	1.24	2,510	0.08	40,160
2 N	1.26	2,820	0.10	43,010

5 X	1.25	2,760	0.09	43,130

Tests on 1¼-inch round bars, supports 12 inches apart.

TABLE II.

Chemical Analysis.

Mark.	Manganese.	Phosphorus.	Sulphur.	Silicon.	Nickel.
1 N	0.460	0.63	0.090	2.07	0.67
2 N	0.455	0.63	0.089	2.08	1.18
3 N	0.450	0.63	0.091	2.05	2.07
4 N	0.444	0.62	0.087	2.02	3.25
5 N	0.444	0.63	0.088	2.10	6.65
3 X	0.450	0.62	0.086	2.12	——

The results would not indicate a marked improvement in the physical strength of the castings, and would bear out the supposition that nickel in cast iron is either not distributed uniformly enough to do much good, or else will find its best use in special classes of the metal freer from the high percentages of impurities incident to the ordinary casting.

It is to be hoped that further experiments can be made to prove just what does happen when nickel is added to cast iron.

*Paper presented before Philadelphia convention of American Foundrymen's Association.

Industrial Progress

CAADIAN MACHINERY will be pleased to receive, as confidential, industrial news of any description, the incorporation of companies, establishment or enlargement of plants, railway, mining or municipal news.

New Plants and Additions.

The Canadian Bag Co. are building a factory at Winnipeg.

A bait freezer will be erected at Lingan, N.S., to cost $3,500.

A biscuit factory will be erected in Toronto to cost $10,000.

A large, modern laundry will soon be erected at Vancouver, B.C.

Peers Bros., Vancouver, will erect a sawmill at Port Moody, B.C.

The power plant for Saskatoon, Sask., will soon be in operation.

The sawmill of Mohr & Co., Kilialoe, Ont., was destroyed by fire.

Alterations to G. S. Britnell's factory, Toronto, will cost $12,000.

McCoskerie's sawmill, at Hartley Bay, B.C., will double its capacity.

The Bell Telephone Co. will install a central energy system in Galt, Ont.

Fisher Bros., Toronto, will erect a galvanized iron warehouse to cost $3,000.

Laidlaw & Watson Shoe Co., Toronto, will erect a factory to cost $12,000.

Fire recently did considerable damage to the power house at Stratford, Ont.

Work is progressing on the new high-pressure plant for the Winnipeg waterworks.

The Eagle Knitting Co., Hamilton, are going to erect a new factory in that city.

The Alberta Portland Cement Co., Calgary, wish to supply power to that city.

The Empire Mfg. Co., Vancouver, will erect a foundry, in that city, to cosy $2,500.

The Cataract Power Co. have the contract for supplying power to Brantford, Ont.

Fire did damage to a mill and elevator at Russell, Man., to the extent of $25,000.

R. Bigley, stove manufacturer, Toronto, will build a new stove foundry in that city.

A two-storey biscuit factory will be built by Symons & Rae, Toronto, to cost $10,000.

The machinery is being installed in the plant of the Western Canneries, at Medicine Hat.

The Bell Telephone Co. have installed a metallic line from Tara to Owen Sound, Ont.

The Ontario Power Co.'s transformer house near Welland Ont., was burned out recently.

The new foundry at Lunenburg, N.S., is nearing completion and will soon be in operation.

Plans are under way for a big iron and steel plant for Vancouver, B.C., to cost $15,000,000.

Fire recently did $15,000 damage to the planing mills of S. Hill & Son, Saskatoon, Sask.

The official tests of the new 800-kilowatt plant at Morrisburg, Ont., were completed recently.

The Bell foundry, St. George, Ont., has been sold to Chapman & Fleury, the price being $25,000.

Work has commenced on the erection of the steel plant of the Coughlan Co., at Vancouver, B.C.

The Brantford Linen Manufacturing Co. are going to transfer their factory to Tillsonburg, Ont.

The new plant for the Hespeler Hoisting Machinery Co., Hespeler, will soon be in operation.

The Canadian Ornamental Iron Co., Toronto, will build a one-storey brick factory, to cost $5,000.

The plant and buildings of the Intervest Peat Fuel Co., Winnipeg, were destroyed by fire recently.

The Stony Lake Navigation Co., Peterboro, Ont., will build a new boat for service on the lakes.

The new power plant at Woodstock was recently put in operation, and is giving entire satisfaction.

The Miramichi Lumber Co. are negotiating for the purchasing of the Clark Spool Mill, Newcastle, N.B.

The electric plant on the Wabi river will soon be in operation, supplying power to New Liskeard, Ont.

It is said that the power capable of being developed at Kakabeka Falls, Ont., is 100,000 horse-power.

The capital stock of the Canadian General Electric Co., Peterboro, Ont., has been increased to $8,000,000.

A local telephone company has been formed at Vancouver, B.C., and will immediately apply for a charter.

The Northumberland & Durham Power Co. are contemplating the transmission of power to Kingston, Ont.

Fire did damage in Janesville, near Ottawa, to the extent of $9,000. The paint shop of A. Proulx suffered.

The Ladysmith Lumber Co. will erect a sawmill near Nanaimo, B.C., to cut 35,000 feet of lumber per day.

The Cataract Power Co. will run a high-potential transmission line from Hamilton to Brantford, Ont.

A telephone signal service is being established on the St. Lawrence river, between Montreal and Quebec.

Cleveland, Ohio, parties will commence to manufacture a full line of paint products at Winnipeg, in 1908.

Consignments of harvesting machinery aggregating three hundred tons, were shipped to Australia recently.

The warehouse of Shim & Son, Saskatoon, was destroyed by fire, and $15,000 worth of goods was destroyed.

The Canadian Pin Co., a new concern, will erect a factory at Woodstock, Ont., for the manufacture of pins.

E. C. Atkins & Co., Indianapolis, Ind., will erect a Canadian branch factory at Hamilton, Ont., to cost $50,000.

Fire did damage to the plant of the Partington Pulp & Paper Co., at Union Point, N.B., to the extent of $3,000.

It is expected that No. 1. factory of the new Siliker Car Works, at Halifax, N.S., will be opened in a few days.

The Canadian Independent Telephone Co., Toronto, is organized, and will erect works in Hamilton or Toronto

The Seechelt Brick & Tile Co., a new company, will erect a brick-making plant at Seechelt, to cost $50,000.

A large force of men are engaged in laying underground cables for the Bell Telephone Company, at Peterboro, Ont.

The New Liskeard Concrete Co., New Liskeard, Ont., are installing a new mixer, and a concrete block machine.

Fire recently destroyed the Maritime Mfg. Co.'s plant at Pugwash, N.S. Loss, , with insurance of $10,000.

A big addition will be made to the coal and furnace docks of the Canadian Northern Coal Co., at Port Arthur, Ont.

The cost of the power plant of the Stave Lake Power Co., Stave Lake, B.C., will be in the neighborhood of $2,500,000.

The Ottawa Pulp & Paper Co. has been formed, to make paper out of refuse spruce and hemlock. The capital is $150,000.

The entire plant of the Standard Brick &

Tile Co., New Glasgow, N.S., was destroyed by fire, entailing a loss of $300,000.

Hamilton purchasers have acquired the timber limits, mill and machinery of McManus & McKelvie, New Liskeard, Ont.

The British Columbia Electric Railway Co., will supply Ladner, B.C., with light. The power is generated at Lake Buntzen.

J. Davidson, Millbrook, Ont., has purchased the lighting plant and has been awarded the contract for lighting the town.

The Kennedy Carbon Light Co. will erect a plant for the manufacture of gasoline lamps and heaters at Port Arthur, Ont.

The Canadian Machine Tool Works Co., Brantford, may erect a plant for the manufacture of [illegible] for use in Canada.

T. Gray & Co., New Westminster, B.C., will erect a sawmill on the Pitt river. The machinery for the mill has been purchased.

Messrs. Mooney, Toronto, are considering the establishment of a large plant in that city for the manufacture of Portland cement.

A company has been formed at Minnedosa, Man., for the development of power there. A hydro-electric plant will be installed.

The Dominion Iron & Steel Co., Sydney, N.S., have received an order from an American concern for one million tons of ore.

The Railway Paint Co., Edmonton, Alta., will build a factory in that city at a cost of $100,000. The company's capital is $250,000.

Operations have commenced on the construction of the new factory for the Imperial Steel & Wire Nail Co., at Fort William, Ont.

The Record Stove & Furnace Co., capitalized at $40,000, will carry on business in Canada. Their headquarters will be at Winnipeg.

A large power plant is contemplated on the Yukon river about 50 miles below Dawson. The initial capacity will be 1,000 horse-power.

The Great West Coal Company has been formed at Port Arthur, to develop 12,000 acres of coal lands recently purchased in Alberta.

W. H. Tamin, of Minneapolis, Minn., has been appointed to have charge of the Port Arthur, Ont., branch of the Barnett-McQueen Co.

The Graham Co., Vancouver, will erect a large mill at the Queen Charlotte Islands. It will have a capacity of 200,000 feet per day.

The power situation in Moose Jaw is reaching an alarming condition. The present plant is incapable of keeping up with the demand.

The Canadian branch of the Royal mint will cost, when completed, about $500,000. The salaries will run as high as $80,000 per annum.

J. B. Pause & Company, Montreal, have been awarded the contract for building a new jail at Montreal, the contract price being

E. H. Keating and Wm. H. Breithaupt, Toronto, have formed an engineering partnership, with offices at Aberdeen Chambers, Toronto.

The Moreton Truck and Storage Co.'s building, Toledo, Ohio, occupied by the International Harvester Co., was destroyed by fire recently.

The Copeland-Chatterson Co., Toronto, will take over the entire business of the Elliott Fisher Billing Machine Co., for the Dominion.

R. Forbes Co., Hespeler, Ont., has secured a Dominion charter and will manufacture textile goods. The capital of the company is $1,000,000.

The Consumers' Gas Company, Toronto, will build a one-storey brick broiler house, condenser house and smokestack, at a cost of $60,000.

It is said that the lumber operators on the branches of the Miramichi river, N.B., will handle 120,000,000 feet of timber this coming winter.

The Wapella Roller Mills, Wapella, Sask., owned by R. J. Lund, were destroyed by fire last week. Loss, $22,000, partly covered by insurance.

The puddling furnaces and rolling mills recently established at Winnipeg make the fourteenth iron and steel plant now in operation in Canada.

The New Brunswick Government has decided to grant to the New Brunswick Petroleum Co. a lease of 10,000 acres of land under the usual restrictions.

M. B. Perine & Co., have taken over the business of the Doon Twine & Cordage Co., Doon, Ont., and will improve the plant at a cost of about $55,000.

United States capitalists are considering the erection of a large dry dock, capable of holding the large vessels on the lakes, near St. Catharines, Ont.

The contract has been awarded to the Canadian Iron & Foundry Co., Montreal, for 21 hydrants and 100 tons of pipe, by the town of St. Mary's, N.B.

The new plant of the Canadian Brass Manufacturing Co. at Galt, is now in full operation, and will manufacture plumbing supplies and brass castings.

The Pennsylvania Railroad Co.'s Altoona shops have added to their equipment two Northern 12½-ton 3-motor electric travelling cranes, 54-foot span.

The Development & Finishing Co., New York, will install a plant in St. Catharines, Ont., for the manufacture of chlorine and alkali, by the Townsend process.

A large plant for the manufacture of glass, tiles and pipes will be established at Morinville, twenty-four miles north of Edmonton, by a San Francisco syndicate.

The Hespeler Furniture Co. are building a large addition to their works, which is now [illegible] and will be in operation in the course of a few weeks.

The second brick plant for Rosthern, Sask., will be erected soon. A company has been formed and a plant with a daily capacity of 60,000 bricks will be erected.

The Canadian Machine Telephone Co. intend erecting a factory which will employ two hundred men. Brantford, Hamilton and Toronto are all after the new industry.

A large Wisconsin wagon company will erect a Canadian branch factory at Winnipeg, to supply what has been their export trade in western Canada for past three years.

The Saraguay Electric Light & Power Co., Montreal, are erecting a new 11,500-volt three-phase transmission line to Notre Dame de Grace, a distance of nine miles.

A syndicate, headed by Walsh & Arnaud, Vancouver, B.C., will erect a large brick plant in Barnaby, near New Westminster, which will have a capacity of 50,000 bricks daily.

Clare Brothers & Co., Preston, are building a new warehouse near their stove foundry. The new building will be 100 feet by 30 feet, and will be used for storage purposes.

The new blast furnace of the Atikokan Iron Co., Port Arthur, Ont., will soon be running at its full capacity. The company is considering the doubling of its plant at Port Arthur.

Plans are being made for the erection of an enormous plant in the Kootenay district for the manufacture of steel rails. It is hoped that the plant will be able to fill orders in two years.

The Canada Woodenware Company, which has been looking for a site for their factory since they were burned out at Hampton recently, has decided to locate at South Bay, near Fairville, N.B.

A St. Paul, Minn., agricultural implement firm, who have enjoyed a large export trade in western Canada for the past four years, will erect extensive factory buildings at Winnipeg, Man.

The North Atlantic Colliers Co., Port Morien, N.S., are enlarging their plant. They have ordered a Babcock & Wilcox watertube boiler. A pump and hoisting engine will be installed shortly.

O. & C. Clarke, Montreal, propose to establish a factory in that city for the manufacture of brass goods, providing the city will grant them a free site, with exemptions and other privileges.

C. J. Wright, Montreal, is proposing to erect a factory for the manufacture of brass goods in St. Catharines, Ont. A free site is wanted, with exemptions from taxation, and other privileges.

The Silica Brick and Lime Co., Parson's Ru[illegible], is turning out 15,000 bricks per day, and is filling an order for one million bricks for the Spencer block being erected at Vancouver.

The British Columbia Electric Railway Co., Vancouver, B.C., are pushing a scheme which supplies electric power to portable sawmills in the forests. It is claimed to reduce the cost of cutting timber.

The Excelsior Factory, operated at Chilliwack B.C., by Messrs. Kipp & Sons, has been purchased by the Barbara Mattress Company, of Vancouver, and the machinery has been removed to that city.

An American syndicate is considering the erection of a smelting plant at Sherbrooke, Que.

The property and effects of the Windsor Foundry & Machine Co., Windsor, N.S., are offered for sale by tender.

A. F. Baeber & Co., Vancouver, have been awarded the contract for the electric appliances for the new C.P.R. Empress hotel in that city. It is one of the biggest contracts of its kind in western Canada.

The installation of a lighting plant at the new factory of the Gilson Company, Guelph, Ont., is being carried out by A. C. Lyons & Company, Brantford, and will be completed by the end of this week.

The rail mill of the Superior Corporation, at Sault Ste. Marie, was opened recently, after a shut-down of two weeks for repairs. One of the furnaces has been relined and the capacity of the plant increased.

Winnipeg is the location selected by New York State glove and mitten manufacturers. A factory is to be started immediately, equipped with the latest labor-saving machinery, with a capacity of 100 dozen per day.

At the organization meeting of the Wolverine Brass Co., Chatham, Ont., the following officers were elected: L. A. Cornelius, president; H. C. Cornelius, vice-president. Claud Cornelius will be manager and superintendent.

It is reported that a large English firm will compete with the Standard Oil Co. for western Canada business. The new company will build a large oil refinery at Vancouver, B.C., with a capacity of one thousand barrels a day.

A telephone company has been formed in Princeton, Ont., to be known as the Princeton-Drumbo Rural Telephone Co. A line will be run connecting Princeton, Drumbo, Eastwood and Gobles. F. J. Daniel, Princeton, is president.

Fort William, Ont., has made definite arrangements with the International Snow Plow Mfg. Co., whereby the company will receive a free site and ten years' tax exemption, in return for the establishment of steel car shops in that city.

The Sutherland Rifle Sight Co., Ltd., who have just completed a new slow-burning building at New Glasgow, N.S., have started part of their equipment and have toolmakers making tools for manufacturing the Sutherland military rifle sight.

Crowland township last week passed a by-law granting a fixed assessment of $20,000 per year to the Bemis Bag Co., of Boston, who will build a million and a half-dollar factory close to Welland, Ont., and agree to employ fifteen hundred hands.

D. Hall and Alex. Robertson have gone into the lumber business, and will build a large lumber and shingle mill at Chilliwack, B.C. They also intend putting in machinery for the equipment of an up-to-date box factory, and will manufacture fruit boxes.

A new company, the Dominion Smoke Consuming Company, is being organized; capitalization $50,000, with head offices in Toronto. The company has applied for an Ontario charter and has purchased the Canadian patents from the National Smoke-Consuming Company, of Buffalo, N.Y.

The largest fire that has happened in New Glasgow, N.S., for years occurred recently, when the magnificent building, plant and machinery of the Standard Brick & Tile Company were burned to the ground, and the great industrial establishment is now a mass of ruins. The loss is $300,000.

The Crow's Nest Coal Co. are said to have exported large quantities of coke to American smelters. As there is a great shortage at home, Canadian industries are suffering for want of coke and the Yale and Kootenay districts, B.C., are calling for enforcement of the penalty clause in the company's charter.

Recent improvements have made the Nova Scotia Steel Company's plant at Sydney, N.S., one of the finest and most modernly-equipped institutions on the American continent. The company's rod mill at Sydney has a record of

production greater than that of any rod mill of the United States Steel Company.

A syndicate of wealthy men, headed by A. D. McRae, of Winnipeg, and Peter Jansen, of Jansen, Neb., have purchased a controlling interest in the Fraser River Saw Mills, Millside, B. C. Large timber holdings have been bought and the total investment made by the McRae-Jansen syndicate is said to exceed $2,500,000.

R. D. Isaacs, St. John, N.B., has submitted to the common council a request for a free site and exemption from taxation for twenty years for a proposed car works to be erected there. He says a company, with $250,000 capital, which will be increased to a million, is behind the scheme. The council referred the matter to a committee.

The Canadian Machine Telephone Co., Brantford, have filed plans for the laying of two miles of underground telephone cable. The cable will be laid in ducts, some eight miles of which will ultimately be constructed. The manholes will all be constructed of concrete. The plans of the company involve considerable expenditure.

The Utah Railway Paint Co., Kansas City, Mo., capitalized at over a quarter of a million of dollars, proposes to establish an immense industry of a similar nature at Edmonton, Alta. The company are said to have located in the vicinity of Edmonton immense beds of a mineral clay, called kaolin, from which paint can be manufactured. The proposed plant will cost $100,000.

The Chicago and St. Lawrence Steam Navigation Company's new steamer, the E. B. Osler, was launched at Bridgeburg, Ont. The Osler has the distinction of being the largest ever constructed in Canada. It has a capacity of 9,000 tons. It is 510 feet long and 56 feet wide, and is built throughout after the most approved modern plans. The launching was witnessed by quite a party of Toronto people.

The new works of the Parkin Elevator Co. at Hespeler, Ont., are completed, and the machinery is now being installed. The machine shop is 60 feet by 150 feet, two storeys high; the foundry, 50x60 feet, in which they have installed a cupola of eight tons capacity. The new works are most complete, and the company will be prepared to do wood-work, electrical work, ornamental iron work on all passenger and freight elevators.

The American Electric Furnace Company is establishing a plant at St. Catharines, where an 80 h.p. Colby induction furnace will be installed, and later on another furnace of the R. Jellin type, requiring 200 electric horse-power, will also be installed. This furnace will yield 1,000 pounds of steel at a single heat, and has a capacity of six heatings during twenty-four hours. A large crane of five tons capacity is being built for the plant by the Niagara Falls Machine & Foundry Company.

John Ballantyne & Co., Galt, have invented and are having patented a self-locking device for the movable side pressure and chip-breaker on molding machines. This invention has proved a great time-saver and will greatly enbance the value of their machines. At first used only on their 12-inch molder on base, a massive machine of 7,200 pounds, it proved such an unqualified success that this enterprising firm are placing it on all their molders and have taken the necessary steps to protect their invention.

Companies Incorporated.

Record Stove & Furnace Co., Winnipeg; capital, $40,000. To deal in and manufacture stoves and furnaces. Incorporators: J. Peters, A. E. Peters, D. I. Welsh, all of Moncton, N.B.

The Peele Oil & Gas Company, Toronto; capital, $10,000. To develop oil and natural gas wells. Provisional directors: F. Watts, H. A. Menet, J. L. Galloway, J. C. Colling, and W. E. Sampson, all of Toronto.

Canadian Gypsum Co., Toronto; capital, $20,000. To manufacture gypsum, gypsum plaster and kindred substances. Incorporators: J. S. Lovell, H. Chambers, Robert Gowans, S. G. Crowell, Walter Gow, all of Toronto.

The Tyrell Cooler & Filter Co., Ottawa; capital, $100,000. To manufacture coolers, filters, and similar articles. Provisional directors; P. D. Herbert, H. W. Tyrell, D. T. Smith, James Herbert and J. R. Osborne, all of Ottawa.

Union Brass Goods Co., Toronto; capital, $150,000. To carry on business as brass and iron founders. Provisional directors: Morley Punshon, Vander Voort, Francis Joseph Stanley, and William Andrew Smiley, all of Toronto.

The Ozone Sterilization Co., Haileybury, Ont.; capital, $100,000. To acquire and operate any processes and inventions for purifying liquids, ores, etc. Provisional directors: W. A. Gordon, R. O. Morrow, F. A. Day, all of Haileybury.

The Dickson Bridge Works Co., Campbellford, Ont.; capital, $40,000. To carry on the business of bridge builders and structural steel manufacturers. Provisional directors: James H. Caskey, Campbellford; William Coates Macann, F. C. Downey, Toronto.

Keystone Lorrain Mining Co., Haileybury, Ont.; capital, $1,000,000. To prospect for and deal in minerals. Incorporators: E. J. DuMee, C. J. Suplee, G. T. Armitage, George G. Thompson, all of Philadelphia, Pa., and G. M. Davis, Wilmington, Del.

The Dominion Oil Co., Hamilton; capital, $100,000. To prospect for and deal in oil, gas, salt and minerals. Incorporators: William Melville McClement, H. Harry Bicknell, D. P. Kappele, Florence Austin and Lizzie Eldon Anderson, all of Hamilton, Ont.

G. A. Rudd & Co., Toronto; capital, $100,000. To manufacture and deal in harness, saddlery, leather and kindred articles. Provisional directors: George A. Rudd, James McGregor Young, John E. Elliott, Gordon C. Rudd and Gregory S. Hodgson, all of Toronto.

Hamilton Steel & Iron Co., Hamilton, Ont.; capital, $5,000,000. To carry on a general rolling mills and smelting business. Incorporators: Robert Hobson, William Southam, John Milne, Albert E. Carpenter, Charles E. Doolittle, Geo. L. Staunton, all of Hamilton.

Standard Sanitary Manufacturing Co., of Pittsburg and Montreal; capital, $250,000. To manufacture plumbers' enamelware, brass goods and supplies. Incorporators: T. C. Collins, J. N. Collins, F. J. M. Collins, P. M. Robertson, H. J. Trihey, all of Montreal.

The Algoma Co-operative Co., Sault Ste Marie, Ont.; capital, $40,000. To sell, manufacture and deal in general wares, hardware, paints, oils, etc. Provisional directors: W. Stringer, J. Cleland, D. Robertson, D. Dewar and D. Donald, all of Sault Ste. Marie.

The Canadian Lash Steel Process Co., Toronto; capital, $100,000. To manufacture and sell iron, steel and other metals and their alloys. Provisional directors: J. A. Macintosh, B. W. Essery, Eleanor J. Potts, J. G. Adair, and John Adair, all of Toronto.

Anthes Foundry, Limited, Toronto; capital, $100,000. To manufacture castings, iron pipe, oil pipe and fittings, and plumbers' and steamfitters' supplies. Provisional directors: Lawrence L. Anthes, William Wallbridge Vickers, and Herbert C. Sparling, all of Toronto.

Ingersoll Sergeant, of Canada, Limited, Montreal; capital, $20,000. To manufacture air compressors, rock drills, pumps and pneumatic tools. Incorporators: H. D. Lawrence, William Morris, A. F. Plant, R. F. Morris, Sherbrooke, Que.; W. E. McIver, Richmond, Que.

Monterey Plumbing Co., Toronto; capital, $50,000. To carry on a general plumbing, steamfitting, heating and lighting business, and to deal in general hardware. Incorporators: Gerard Ruel, G. F. Macdonnell, A. J. Mitchell, F. C. Annesley, Robert P. Ormsby, all of Toronto.

National Oxide Paint & Color Co., Hamilton, Ont.; capital, $50,000. To manufacture paint pigments, colors, oils, paints, varnisbes, and japans. Provisional directors; George Stroud, G. F. Webb, Helena O'Sullivan, T. J. O'Sullivan, and Alfred Stroud, all of Hamilton, Ont.

The Dominion Nickel Copper Co., Toronto; capital, $10,000,000. To carry on the operations of a mining, milling, reduction, and development company. Incorporators: James Houston Spence, Ada May Duncan, Lillian M. Heal, Charles E. Freeman, Gertrude E. Jamieson, all of Toronto.

L. H. Hebert & Co., Montreal; capital, $350,000. To carry on the business of ironmongers and merchants in bardware, paints, oils and chemical compounds. Incorporators; Louis H. Hebert, Alfred Jeannotte, Eugene Poitevin, Gustave Busseau, Montreal; Joseph E. Theriault, Joliette, Que.

The New Liskeard Concrete Co., New Liskeard, Ont.; capital, $40,000. To manufacture concrete cement, artificial stone and kindred materials. Provisional directors; S. Jewell, V. E. Taplin, W. H. Carruthers, W. V. Cragg, A. McKelvie, J. E. Whyte and F. L. Smiley, all of New Liskeard, Ont.

The Jenks Dresser Company, Sarnia, Ont.; capital, $50,000. To carry on the general manufacture and sale of iron and steel work. Provisional directors: William G. Jenks, Andrew A. Dresser, Roy M. Norton, all of Port Huron, Mich.; Merton Fuller, Richmond, Mich., and Hiram Manning, Sarnia, Ont.

Ideal Foundry Co., Toronto; capital, $100,000. To engage in the business of general foundrymen and to manufacture cast or wrought iron, steel, brass, aluminum or composition specialties. Provisional directors: Henry Edward Pearce, William Henry Smith, Arthur Gate, Matthew Irving and William Baggs, all of Toronto.

Simplex Gas Co., Toronto; capital, $40,000. To manufacture under Colwell's patents the Simplex gas machine; to manufacture gas burners, stoves, heaters, ranges and hardware, and mechanical specialties. Provisional directors: Walter Ernest Colwell, Harry Herbert Colwell, Oakville, Ont., and Henry H. York, Toronto.

Building Notes.

An armory will be erected at Medicine Hat, Alta.

St. Joseph's church, Sydney, N.S., will be rebuilt.

H. Gleiser, Oxbow, Sask., will build a new hotel.

The new collegiate school at Ottawa will cost $225,000.

Robt. Shaw, Oxbow, Sask., will erect a new business block.

R. Cassidy, Vancouver, will erect a block, to cost $250,000.

A. Peters will erect a hotel in New Westminster, to cost $10,000f

A Masonic hall will be erected at St. Thomas, Ont., to cost $10,000.

A new Anglican church will be erected at Elmwood, Man., to cost $5,000.

An Oddfellows' hall, costing $30,000, will be erected at Strathcona, Alta.

Seymons & Roe, Toronto, will erect a brick dwelling, at a cost of $10,000.

Rogers & McKay, Vancouver, will build a residence, at a cost of $12,000.

Yuen Chong, Vancouver, B.C., will erect a $12,000 business block in that city.

An addition will be built to the Windsor hotel, Peterboro, Ont., to cost $24,000.

The Imperial Bank will erect a new building at Edmonton, Alta, to cost $90,000.

E. Hobson, Vancouver, B.C., will build an apartment house, at a cost of $12,000.

H. Dorenwend, Toronto, will erect an apartment house in that city to cost $20,000.

A new home, to be erected for the Seamen's Mission, St. John, N.B., will cost $15,000.

The Anglican parish of St. Albans, Burnby, B. C., will erect a church, to cost $2,000.

Tenders are invited by T. Gillespie, Peterboro, Ont., for the erection of a Baptist church.

The new Protestant school, which was recently opened at Delorimier, Que., cost $15,000.

P. Roach, Toronto, will build three attached two-storey brick dwellings at a cost of $10,000.

A new business block will be erected in Vancouver by W. Hepburn, at a cost of $22,000.

J. Y. Griffin Company will erect a cold storage block at Edmonton, Alta., to cost $100,000.

The Crystal Theatre Picture Show will erect a theatre in Moncton, N.B., to accommodate 2,000.

The Bank of Commerce will build a branch on Yonge street, opposite College street, Toronto.

T. Gingras, Toronto, will build four pair semi-detached houses, at an aggregate cost of $14,500.

S. J. Castleman, Vancouver, will erect a six-storey business block, to cost approximately $100,000.

C. R. S. Dinnick, Toronto, will erect six pair semi-detached brick residences, at a total cost of $30,000.

The congregation of Paisley St. Methodist church, Guelph, will erect a new edifice, at a cost of $10,000.

W. O. McTaggart, Toronto, will build three three-storey brick stores and dwellings, at a cost of $12,000.

Harry Weinberg, Toronto, will erect a large store on the corner of Yonge and Edward Sts., at a cost of $30,000.

The Nelson Theatre Co., Nelson, B.C., will erect a large theatre in that city. C. W. Busk is one of the directors.

The J. Y. Griffin Co., Edmonton, Alta., will erect a large office block and cold storage warehouse, at an estimated cost of $100,000.

L. C. Sheppard, Toronto, will build seven pairs semi-detached two and one-half-storey brick dwellings, at a total cost of $25,000.

The J. Y. Griffin Company will erect a large office block and storage house in Edmonton, Alta., to cost in the neighborhood of $100,000.

The barns of the Macdonald Agricultural College, St. Anne de Bellevue, Que., which were recently destroyed, at a loss of $35,000, will be rebuilt.

The value of Vancouver building permits for the month of August was $708,775, being an advance of 131 per cent. over the $306,925 recorded for the corresponding month last year.

Municipal Undertakings.

A new school building will be erected at New Westminster, B.C.

Public buildings will be erected at Neepawa, Man., and Selkirk, Man.

Moose Jaw, Sask., will raise $90,000 for a municipal lighting system.

The town of Gracefield, Ont., will install a municipal waterworks system.

A by-law was passed in Toronto, providing $781,121 for waterworks extension.

The foundations have been laid for the new civic buildings at Saskatoon, Sask.

Surveys are being made for the new Government telephone system for Winnipeg.

The town council of Hull, Que., has decided to erect three new fire halls, to cost $25,000.

The ratepayers of Cornwallis, Man., are petitioning for a municipal telephone system.

The by-law for 00,000 for electric light extension in Moose Jaw passed the first reading.

J. B. Beverage, Chatham, N.B., is considering the erection of a pulp mill in Newcastle, N.B.

The Government will build a large concrete dam near Trenton, in connection with the Trent canal.

The town of Orillia, Ont., will make a profit this year of $9,000 from its light and power plant.

The city of Revelstoke, B.C., is calling tenders for the enlargement of the city hydro-electric plant.

The council of Bracebridge, Ont., are considering the propositions of a firm manufacturing steel chairs.

The ratepayers of Prince Albert, Sask., will vote on a by-law for $29,000 for sewerage improvements.

The new light plant for Claresholm, Man., has been completed. It replaces the one destroyed by fire recently.

A by-law was passed at Islington, Ont., for the issue of debentures to the extent of $18,000 for a school house.

Tenders will be asked by the Winnipeg Board of Control for a building in connection with the waterworks, to cost $20,000.

A provincial asylum will be erected by the Government of British Columbia, at Coquitlam, B.C. It will cost $200,000.

Bids will be asked by the Winnipeg Board of Control for a $40,000 bridge in connection with the Point du Bois power plant.

The ratepayers of North Battleford, Sask., have sanctioned a by-law for $10,000 for a bonus for a new flour mill and elevator.

The town of Kenora, Ont., is contemplating the installation of an arc lighting system, at a cost of $4,000, and an electric pump for the waterworks.

The council of Ottawa, Ont., are considering the erection of a municipal lighting plant, to be put in operation when the Hydro-electric contract expires.

The ratepayers of the village of Tetreauville, Que., will vote on a by-law for issuing $15,000 of debentures and establishing a municipal waterworks system.

The ratepayers of Aylmer, Ont., have petitioned the council to raise $10,800 for additional water supply, and to furnish a site for the Canadian Condensed Milk Co.

The contract for the erection of the telephone exchange for the Manitoba Government, at Winnipeg, has been awarded to J. J. Kelley, Winnipeg, the figure being $97,172.

London, Ont., has decided to submit the Komoka water scheme to the people in two by-laws, one to provide $293,500 for extending the domestic water supply, and one for $182,000, to provide for a hydraulic power plant and reservoir.

A new court house and a new registry office will be built at Sudbury, Ont. The contract for the court house has been awarded to M. Healey, Toronto. The registry office will be built by the O'Boyle Construction Company, North Bay.

Mining News.

Part of the plant of the Irondale Smelters, Port Townsend, B.C., was destroyed by an explosion.

The Dominion Iron & Steel Co., Sydney, N. S., will work the Wabana iron ore fields, near Sydney.

A large ore crusher will be added to the plant of the Granby Co., at the Boundary mines.

The Salt Lake Smelting & Refining Co. will commence the erection of their smelter at North Cobalt, soon.

During the first month of the last half of the year the Boundary smelters, B.C., reduced 150,000 tons of copper ore.

The plant of the Algoma Steel Co., Sault Ste Marie, has shut down on account of the lack of ore and need of repairs.

Owing to the shortage of coke in the west, it is feared that the furnaces at the Trail smelter, near Rossland, will have to shut down.

It has been found possible to turn out pig iron capable of being turned into the best quality of Bessemer steel, at the Atikokan furnace, Port Arthur, Ont.

The successful experiments made by the Dominion Government with the Heroult electric smelter, at Heroult, Cal., have been corroborated. The process is found satisfactory and much cheaper than usual methods.

The Canadian Smelting and Refining Co., Sault Ste. Marie, will erect a large smelter and expect to have the plant in operation within six months. $1,000,000 is behind the enterprise.

A large and enormously rich deposit of iron ore has been discovered at Lakevale, Antigonishe, N. S. The property is said to be one of the best yet found and is owned by American capitalists.

The directors of the Golden Peak Mining Company, Larder Lake, Ont., have decided to install a mill of 20 stamps on their property. The mill will be put in as soon as the road from Boston to Larder Lake is completed. This will be in about a month.

It is stated authoritatively that a company, called the Muggley Concentrators, Limited, will put in a hundred-ton concentrating mill shortly at Cobalt. The mill will use twenty screens and crushing rolls to increase the capacity. Owing to the delay in getting in machinery it is probable that the plant will not be running before January.

Railroad Construction.

The C.P.R. will spend $100,000 in additions to their shops at Winnipeg.

A new electric line is proposed between Wallaceburg and Petrolea, Ont.

The roadbed of the G.T.P., east of Edmonton, is ready for the steel.

Work on the Goose Lake, Sask., branch of the C.N.R., was commenced recently.

Work has commenced on the construction of the new C.P.R. depot at Saskatoon, Sask.

Construction has commenced on the electric line from Eburne, B.C., to New Westminster.

Work is progressing rapidly on the construction of the Brandon-Regina line of the C.N.R.

The Michigan Central will construct a line from Charing Cross, Ont., to Chatham, Ont.

The G.T.R. will proceed without delay to construct the line from Kingston to Ottawa Ont.

The C.P.R. are installing telephones along the line between Fort William, Brandon and Winnipeg.

The B. C. Electric Railway will spend $350,000 in improvements to their New Westminster premises.

A new flour shed is about to be erected by the I.C.R. at St. John, N.B., at an expenditure of $20,000.

The grading is almost completed on the C. N.R. branch from St. Jerome, Que., to the main line.

The Canadian Northern is considering the building of an air line from Brockville to Ottawa, Ont.

The contract for the new I.C.R. station at Amherst, N.S., has been let to LeBaheo, of Moncton, N.B.

There is a rumor that the proposed Hamilton-Galt electric line will be pushed through without delay.

The new Guelph to Goderich line of the C. P.R. was opened recently. Trains are now running regularly.

Construction will begin on the Kootenay Central branch of the C.P.R. from Golden, B.C., to Crow's Nest Pass.

The Ottawa Electric Railway Company propose to extend their line to the Experimental Farm, near that city.

Active operations are in full swing on the construction of the new addition to the G.T.R. shops at Stratford, Ont.

The contract for the new roundhouse for the C.N.R., at Brandon, has been let to the Sharp Construction Co., Winnipeg.

The Canadian Pacific will erect an extensive terminal station at Fort William, Ont. They will build a large dock.

The Canadian Northern will build a line from Vancouver to northern British Columbia, to connect with the main line.

The Chicago, Milwaukee and St. Paul Railway will build to the coast and run a line from Seattle to Vancouver.

The C.P.R. and Brandon, Saskatchewan and Hudson Bay Railroads will build a line connecting their yards through Brandon.

The contract for the G.T.P. bridge over the Kaministikwia river has been awarded ta Wylie & Belfour and the Canadian Bridge Co.

The construction has commenced on the line of the B. C. Electric Railroad, from New Westminster to Chilliwack, to cost $2,500,000.

The contract for the G.T.P. bridge over the Kaministikwia river, Fort William, has been awarded to the Canadian Bridge Company.

The N. St. C. & T. Ry. Company's new power house at Thorold, Ont., is now under construction. It will cost $50,000, and develop 1,500 horse-power.

Contracts for the erection of a $[illegible],000 addition to the car shops at London, have been let to Mr. John Hayman, and work will be commenced immediately.

The Ontario Municipal and Railway Board have approved the plans for the completion of the line from Pembroke to Gold Lake, on the Pembroke and Gold Lake Railroad.

The rebuilding of the railway bridge across Rice Lnke, near Port Hope, Ont., and the rehabilitation of the old Cobourg and Peterboro Railway, is being seriously discussed.

The Intercolonial Railway have recently given to the Rhodes, Curry Co., Amherst, N.S., the contract for 260 flat cars, 400 box cars, 25 refrigerator cars and four conductor's vans.

The Southwestern Traction Company's line, after being tied up for three weeks, on account of the recent fire in the car barns, is now in full operation between London and St. Thomas.

The Canadian Railway Commission have issued new regulations regarding the watching of trestles and bridges, fire protection for same, watching of tracks and fire protection for cars.

The C.P.R. will build two large steamers of the Princess Victoria type for service on the Pacific. The builders are from the Fairfield Shipbuilding & Engineering Co., Govan, Scotland.

The British Columbia Electric Railway Co., Vancouver, B.C., are pushing a scheme which supplies electric power to portable sawmills in the forests. It is claimed to reduce the cost of cutting timber.

The British Columbia Electric Railway have ordered 26 cars for city service. In order to turn these out, the number of men employed at the car shops will be doubled and two shifts organized to work night and day. The cars cost $6,000 each.

The C.P.R. are fitting up a plant at Vancouver, B.C., where they intend to generate Pintsch gas, to be utilized in illuminating passenger coaches on their western lines.
completed for the C.P.R.

The C.P.R. are contemplating building a million-ton coal dock at Fort William. The entire yards of the company will be remodelled at great expense, nnd the plans, when carried out, will make Fort William the finest inland steamship and railway terminal in the world.

The C.P.R. will spend over $1,000,000 in constructing two tunnels through the Rockies near Field, B.C. One will be to the north of the Kicking Horse river and will be 3,400 feet long. The other will be south of the river and will form practically a complete circle through the heart of Cathedrnl mountain. It will be 3,800 feet long.

Eight new engines of the "consolidated" type have been received at the London, Ont., roundhouse of the Grand Trunk, and are now being operated on that division. As a result, the situation has been greatly relieved. The engines are of the heaviest type in Canada. They are able to haul 90 loaded cars and have four drive wheels. They are much heavier than the locomotives of the "900" and "800" class and will be a great addition to the freight service.

Costly Lawsuit.

In the lawsuit of the Dominion Iron & Steel Co. against the Dominion Coal Co., Sydney, fore the courts amounted to $[illegible]
N.S., it was decided that the Dominion Coal Co. committed a breach of contract in supplying a grade of coal unfit for the purposes for which it was required.

It is announced that the cost of this case decision provides for an arbitrator to determine the damages that the Coal Company must pay, and it is said that the Coal Company will appeal. For every hour the court sat, the suit cost $1,000. The case was purely a business disagreement and had it been settled by arbitration the costs would have been much less and the results eminently more satisfactory.

New Plant for Fort William.

The Imperial Steel & Wire Company's new plant, at Fort William, is now under construction, the site being alongside the new works of the Canada Iron Foundry Company. The main building is to be 600x70 feet, while a warehouse will also be erected, 60x200 feet. The buildings will be of cement, and will be constructed in time to have machinery installed next spring. It is expected that 250 men will be employed at the works. Alderman R. S. Piper, hardware merchant, presented a handsomely decorated shovel, which was used by the wife of the general manager, Major J. A. Currie, in turning the first sod.

New Foundry and Machine Shop.

McLenn & Holt are just completing a new foundry and machine shop. It will be equipped to carry on a very extensive business. The cost is not mentioned. With the installation of an up-to-date plant in this building the firm will be in a better position than ever before to turn out "Glenwood" ranges and all lines of stoves and furnaces.

A New Departure in Building.

Dr. Alexander Graham Bell has just completed, on Lookout Mountain, at his summer residence, near Baddeck, N.S., a lookout tower, built on the tetrnhedral principle, said to be the first tower of its kind in the world. A tetrahedron is simply a three-sided pyramid, its three sides and base all being equilateral triangles. Those in the tower are made each of six pieces of galvanized half-inch pipe, four feet long, and four nuts, into which the pipes are screwed, and the tower is simply a giant tripod built up of these, Such a structure, Mr. Bell says, is lighter and stronger than any other, more quickly and more cheaply built, and requires no skilled labor. Patents on the principle and on the nuts used at the corners, are being taken out.

New Cars for C. P. R.

The C.P.R. will build an entirely new type of car for use on the transcontinental trains. This car will be modelled somewhat on the lines of a new type on the Southern Pacific Railway. One great feature will be windows 54 inches wide and reaching to the roof; in fact, the whole sides of the car will be practically made up of plate glnss, so as to give the best possible opportunity to travelers of seeing the sights along the railway. There will, in addition, be a big observation platform, where people can sit in the open in easy chairs in fine weather.

The interior of the car will be divided into three compartments. At one end it will be furnished with easy chairs very much after the style of the present parlor cars. In the middle will be a library, with all the latest books, magazines and newspapers, and also a counter where light refreshments can be obtained: at the other end will be n very large, airy, and comfortable smoking car, of the same size and fitted up in very much the same way, observation windows and all, as the parlor end of the car. These cars will be known as "Library, Club and Observation Cars," and enough of them are to be built this winter to put one on one through train a day each way next season.

To Prevent Collisions.

Recently the Intercolonial Railway have been making exhaustive tests of the new device invented by Mr. H. W. Price, of Toronto, for the prevention of both head-on and rear-end collisions. The tests were carried on at Moncton and two trains fitted up with the instruments were started from stations some distance apart. When they came to the block of the signal system the brakes were automatically applied and the train stopped. The tests were satisfactory in every way, and the adoption of the system by the I.C.R. is quite probable.

ABOUT CATALOGUES

FURNACES.—Two bulletins on rod and bolt heating furnaces, along with prices, manufactured by Rockwell Engineering Co., New York city.

FINISHING GAS ENGINE PARTS.—Sheet No. 76 of Gisholt Machine Co., Madison, Wis., showing operations for finishing pistons and piston rings.

DROP FORGING.—A handsome booklet of E. N. Bliss Co., Brooklyn, N.Y., illustrating and treating of their forging drop-hammers, and also presses.

E. N. BLISS MEMORANDA.—A very neat little vest-pocket booklet illustrating and describing Bliss presses, and containing pages for memoranda at the back.

[illegible]T VISES.—Booklet issued by Emmert Mfg. Co., Waynesboro, Pa., containing illustrations, descriptions and price lists of the Emmert patent universal vises.

WRIGHT'S TAPER-ROLLER BEARINGS.—Handsome catalogue of these bearings, made by Canadian Bearings, Ltd., Hamilton. It is 6x9 inches, and is well illustrated.

POWER TRANSMISSION MACHINERY.—Catalogue No. 73 of the Link Belt Co., Philadelphia, concerning their conveying machinery. It is well illustrated, 15 pages, 6x9 ins.

[illegible]TH GAS POWER CO.—Catalogue of producer gas plants of the Smith Gas Power Co., Lexington, O., of whom E. S. Cooper, 128 Adelaide St. E., Toronto, is Canadian agent.

PNEUMATIC TOOLS.—A 48-page catalogue of pneumatic tools issued by the Dayton Pneumatic Tool Co., Dayton, Ohio. The different [illegible]es of hammers, riveters and caulking hammers are clearly illustrated.

[illegible] CUTTERS.—A neat, 16-page pamphlet issued by the Landis Machine Co., Waynesboro, Pa., describing their bolt-cutters and threaders. The many exclusive features are fully explained and each type is clearly illustrated.

[illegible] ENGINES.—A booklet of the De La Vergne Machine Co., New York, describing their two-cycle vertical oil engines, 7½ and 15-horse-power. There are several illustrations. The engine is designed for kerosene and cheap oils.

[illegible]ING WHEELS.—Complete and handsome catalogue of the Norton Co., Worcester, Mass., containing illustrations, descriptions and price lists of all kinds of grinding wheels and machinery. Any interested in this class of machinery should not be without it.

WIRE DRAWING MACHINES.—Two catalogues issued by the German firm, W. Gerhardi, Ludenscheid, Germany. There is an 8-page booklet describing their No. 0 machine, fully describing it, and with several cuts. They also issue a complete catalogue of wire-drawing, galvanizing and rolling mill machinery. It is very tastefully arranged and profusely illustrated.

Canadian Electrical Exhibition

The Canadian Electrical Exhibition, the first of its kind in seventeen years, was held in Montreal from Sept. 2 to 14. In the brilliancy and interest of exhibits in the elaborateness of arrangement, and in the large and distinguished attendance, it is seriously doubted whether this exhibition has been surpassed ever in America. Everything electrical from the smallest electric globe to the gigantic generator of Allis-Chalmers-Bullock Limited, was on exhibit, and every spectator demonstrated deep interest in the various applications of electricity displayed. The Exhibition was officially opened on Monday, Sept. 2, and formally opened Thursday evening following, by Hon. Lomer Gouin, Premier of Quebec.

Amongst the specially interesting features of the show were the Dancing Skeleton (an ingenious arrangement and manipulation of electric lights), artificial lightning, Marconi wireless telegraph stations, with band concerts every evening. All the leading manufacturers of electrical apparatus and supplies in Canada were represented.

CANADIAN ELECTRICAL EXHIBITION—Exhibit of Allis-Chalmers-Bullock, Montreal.

Allis-Chalmers-Bullock, Limited.

The feature of the display made by Allis-Chalmers-Bullock, Limited, was its solid and substantial appearance, recalling the merits of motor, generators, and other machinery made by this company in Montreal. For example, there was a 225 K.W. belled alternating current generator with direct connected exciter in operation. The company had also a number of workmen at work building a 300 K.W. waterwheel type alternator to operate under the enormous pressure of 11,000 volts.

The company brought, too, a number of the winding department girls to show how induction motors are built up from the point where the wire is insulated until the motors are ready for operation which attracted the attention of both engineers and the general public.

A practical use to which one of their induction motors was put was to drive a Worthington centrifugal pump, built by the John McDougall Caledonian Iron Works Co., Limited, showing on a small scale the motor and pump of 5,000,000 gallons capacity, at the McTavish street station of the Montreal Water Works. The fountain in the centre of the exhibition, with its multicolored rays, was still another example of the use their constant speed induction motors may be put. The lighting transformers, which disfigure our streets and walls are, however, a necessary evil under modern conditions, and of these the company showed an interesting line, running from one to 25 K.W.

Canadian General Electric Co.

Probably one of the most interesting exhibits at the show was that of the Canadian General Electric Co. for the reason that not only did their exhibit demonstrate their ability to manufacture almost every line of electrical apparatus in use but in this exhibit they catered to the average householder. Their electric kitchen was certainly a wonderful exhibit. Their demonstrators were brought up from Jamestown Exhibition and were demonstrating what could be done in the way of cooking and baking all kinds of delicacies for the table. Their electrically driven bench drills and breast drills were certainly marvelous, and show how rapidly machine shops could increase the efficiency of their plants.

Probably one of the most remarkable exhibits of the Canadian General Electric Co. was that of their lighting. They not only showed the G. E. M. high efficiency lamps in all candle powers, but are also showing the Nernst lamp, and in addition to this the Tungstein lamp.

They also exhibited all types of alternating current and direct current motors as used in the city of Montreal in sizes from 1-16 of 1 h.p. up to 10,000 h.p.

They also exhibited the Mercury arc rectifier panel, which converts alternating current into direct current, and which is one of the very latest systems of modern arc lighting in use to-day.

Canadian Westinghouse Co.

The name "Westinghouse" is almost synonomous with progress in the most important branches of electricity, and this is one of the many reasons why the booths of the Canadian Westinghouse Company attracted so much attention at the big show.

One of the first things that attracted the casual visitor to the Westinghouse booth was a huge 1,500 horse-power railway type generator, which the company has manufactured for the Montreal Street Railway's new big powerhouse at Hochelaga. There was also on view a 4,000 horse-power transformer.

Then, again, the Westinghouse Company showed some very splendid types of electric lamps, pre-eminent among which is the one known as the Nernst. This lamp, in addition to being placed throughout the large booths of the Westinghouse Company, was used for the general lighting of the whole Drill Hall.

In the centre of the Westinghouse booth was an immense static electric sign which was operated with a pressure of 40,000 volts.

Near the main entrance the Westinghouse Company had constructed the fore part of an electric car equipped with all the Westinghouse air brakes

and other apparatus that is now so commonly used on all electric cars and railway trains. Mr. H. D. Bayne, manager of the Canadian Westinghouse Co., was also a director of the Canadian Electrical Exhibition Company, and much of the success of the first show was mainly due to his efforts and enterprise.

Belliss & Morcom.

A well-known firm of engine builders for electric service in England are Messrs. Belliss & Morcom, Limited of Birmingham. Independent statistics show that more than half of the steam-driven electric stations in Great Britain are using Belliss engines—that this firm are realizing the importance of the Dominion as an engineering field was evidenced by their exhibit at the Electrical Show. Their booth was in charge of Messrs. Laurie & Lamb, 212 Board of Trade Building, Montreal, a firm of engineers whose members have been closely identified with power station work for nearly 25 years.

The Belliss exhibit was unfortunately without the engine which they had expected to have ready to show there, but in its place they had a very suggestive display of photographs of some large installations.

The special features of the Belliss engine are well known, for instance the system of forced lubrication originated by this firm in 1890 by which it is continuously supplied to the bearings under a presure of 15 or 20 lbs. to the square inch, thus ensuring a constant film of oil between the bearing surfaces.

This system has since been fitted to upwards of 3,300 Belliss engines, aggregating 600,000 b.h.p. The results are remarkable, as the wear on brasses has been reduced to practically nil—a case in point being a 220 b.h.p. engine which, after five and a half years' constant service in Croydon Electric station, showed an actual wear on main bearing of only .0025 inch.

The space occupied for horse power by the Belliss engine is very small, a 500 K.W. Belliss set taking up no more floor space than a steam turbine.

The Northern Electric & Mfg. Co. Exhibit.

The exhibit of the Northern Electric & Mfg. Co., of Montreal, at the Exhibition, was one of exceptional interest to those who were connected in any way with telephone or fire alarm affairs.

The telephone apparatus was a complete exhibit of modern switchboards from a small ten line magneto board for rural exchanges to the very latest type of central energy switchboard in use in all of the largest cities. Telephones of several types designed for use under all sorts of conditions from a rural party line of twenty-five subscribers to one for use on a large ten thousand line system was the most attractive feature of the exhibit.

This company also manufactures a very complete line of fire alarm apparatus, consisting of signal boxes of several types, suited to systems of all sizes. Registers, gongs, indicator and central office equipment. The city of Montreal is equipped with apparatus manufactured by this company.

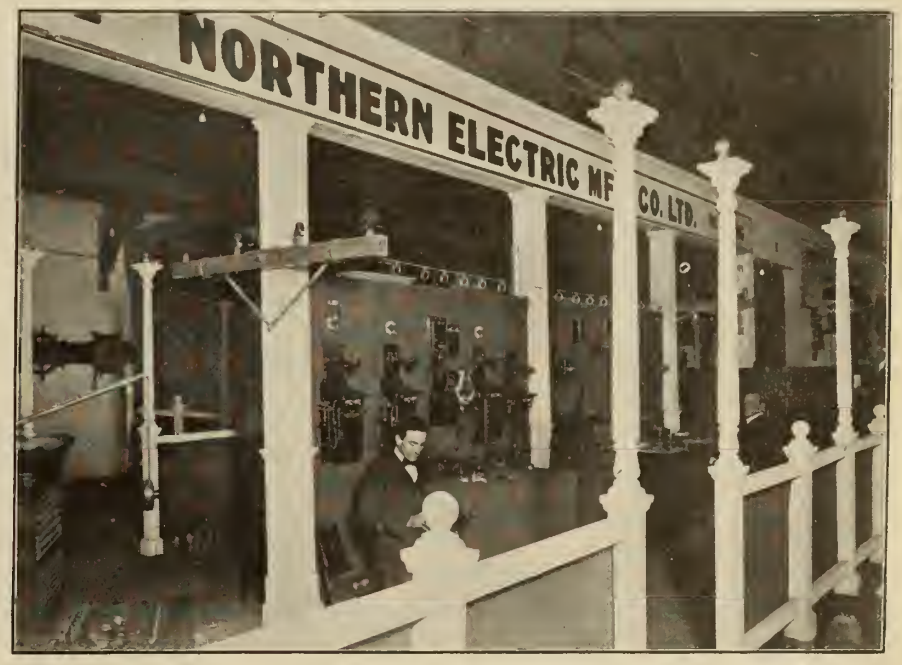
Another interesting feature of the exhibit was the complete line of condit oil, immersed switches and circuit breakers. The Northern Electric & Mfg. Co. are the Canadian selling agents for these switches.

Another feature of this exhibit was the line of Vulcan electric soldering tools, shown in sizes and shapes especially adapted to various classes of work in the telephone business, where uniform and reliable results are absolutely necessary. The Northern Electric & Manufacturing Company has secured the Canadian general agency and manufacturing rights for these thoroughly practical and high-grade tools, the advantages of which are so fundamental that their general adoption in place of furnace-heated coppers is secured. A 24-inch soldering tool of only ½-inch diameter, for use in congested multible switchboard repairs, is a very interesting example of the unequaled adaptability of these electrically self-heated tools.

Robb Engineering Co.

This company's booth at the Electrical Exhibition attracted a great deal of attention, it being the only steam engine exhibit at the show. They exhibited one of their Standard 12 x 12 Robb Armstrong Automatic Side Crank Engines, direct connected to 50-k.w. generator, which is to be used as an exciter unit in connection with four 1,000 h.p. cross compound Corliss Engine direct connected to alternating generator, being installed at the Canadian Pacific Railway Co.'s Angus Shops.

Also one of their Standard Robb-Armstrong Vertical Single Crank High Speed Engines, which they manufacture in various sizes, was exhibited. The engine is of the enclosed, self oiling type, and especially arranged for direct connecting to generators, fans and cent



CANADIAN ELECTRICAL EXHIBITION—Exhibit of Northern Electric Mfg. Co., Montreal.

rifugal pumps, as well as for belted operation.

They also showed a working model of the Robb-Armstrong Corliss Valve Gear, which was especially interesting to engineers, it being a positive-driven motion, requiring no latches, springs, or delicate parts, such as are used in the old type Corliss Valve, while at the same time a motion is obtained precisely the same as that invented by Geo. H. Corliss. An engine fitted with this valve gear can be run from 75 to 175 revolutions per minute.

The engine parts and photographs of some of the numerous plants installed by this company are worthy of mention and show the extent of their work.

The exhibit was in charge of Alister MacLean, resident engineer, Robb Engineering Company, Montreal.

Canadian Rand Co.

The practical demonstrations of working machinery which the Canadian Rand Company are placing before the public, served to make this enterprising concern one of the central points of interest at the Electrical Show. There was shown, in constant operation, a small motor-driven air compressor, for use in situations where compressed air can be utilized as power, or as a means of cleaning out motors. The latter point was emphasized by the official in control of the exhibit. The great cause of motors burning out is the presence of dirt and dust, mixed up with the wiring of the motor. As has been the experience of a great many, this foreign substance sooner or later catches fire, and the electrician is called in for the expensive job of re-widing. By an occasional blowing out with the air compressor all this could be avoided. The work of this remarkable power formed one of the best features of the show.

CANADIAN ELECTRICAL EXHIBITION—Exhibit of J. A. Dawson & Co., Montreal.

J. A. Dawson & Co.

One of the most attractive and busy booths at the show was that of J. A. Dawson & Co., admirably located near the front entrance of the hall. As the picture will indicate, their booth was a mass of well displayed electrical novelties of many varieties. Flowers, bunting and prettily arranged lights and globes made a very handsome effect. Their especial lines, such as electrical railway materials, insulating joints and electric specialties were prominently displayed. The well known Macallen goods, for which they are the agents, received much attention. Among these goods were the giant strain insulators, all the various curve suspensions, and cap and cone material, porcelain guard wire insulators, splicing sleeves, trolley frogs, turnbuckles, etc. They also carry a full line of gears and pinions of the different standard types. In fact, no electrical man could pass without calling, as a competent staff of attendants were busy. Mill supplies were on exhibition, also motors and generators of various sizes and special lighting systems to suit all sized institutions and factories. A splendid array of car heating apparatus—that is, electrical apparatus—was on view and interested large numbers. Added to these was a fine display of the Crouse-Hinds Imperial Arc Headlights. Many smaller articles were noticeable, such as wrenches, the celebrated Jackson brand with interchangeable parts, etc.; also the D. & T. anchor drive and twist—in fact, a diversity too numerous to mention. A catalogue for any of these lines will be sent to all applicants, and these are worthy of immediate attention. The Dawson Co. began business in Montreal many years ago and have steadily grown in public favor. Their address is 148 McGill Street, right in the heart of the best business section, and all enquiries receive prompt and careful attention.

Exhibit of the Packard Electric Co.

The chief features of the Packard Electric Co.'s exhibit were the Jandus alternating current series arc-lighting system, with regulators for street lighting; Jandus line of ceiling and column gyrofans; Crocker-Wheeler dynamos and motors, with alternating and direct current and controlling devices; a full line of America switchboard type and portable electrical measuring instruments. The Packard Electric Co. have the agency for all the above lines. They showed their own new design of alternating current, induction motors, and core type transformers, the Standard Incandescent lamp in all types, also recording Wattmeters of switchboard type, and regular house type.

Canadian Fairbanks Co.

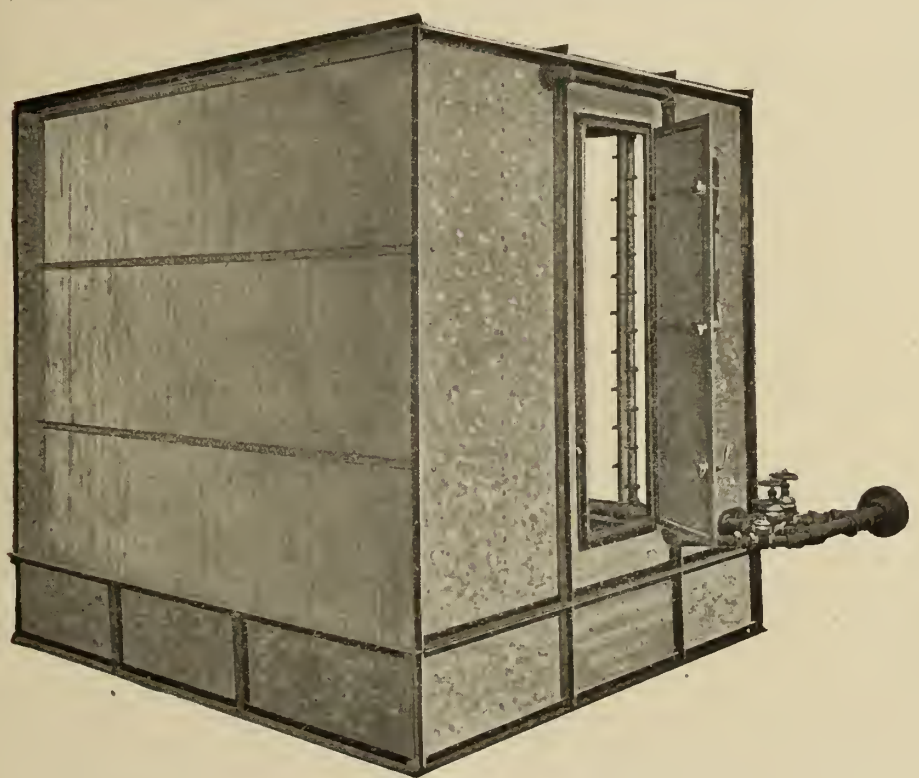
Another exhibit which attracted a great deal of attention was that of Canadian Fairbanks Co., one of the features of which was a four-ton Yale and Towne electric 220-volt, 22-foot life hoist, suitable for use in factories and warehouses. Besides this were a small Fairbanks-Morse engine running a dynamo and pump adapted to lighting and water supply, and Fairbanks-Morse dynamos.

Canadian Buffalo Forge Co.

The exhibit of the Canadian Buffalo Forge Company was a very interesting one, as it gave the visitor a chance of inspecting some of the latest devices used in ventilating purposes. The Canadian Buffalo Forge Company has already equipped a number of buildings in Montreal, including the St. Paul's Hospital, the Western Hospital, the McGill Union and the new McDonald Engineering Building.

In the Buffalo air washer and humidifier the air is brought into direct contact with water spray. After leaving the intake grating the air is led directly to the air washer and there is sprayed by closely spaced nozzles, ejecting each between one and one-half and two pounds of water per minute, in the direction of air travel. The air then encounters the eliminator plates, which remove the free moisture from the atmosphere, allowing it to retain only the amount dictated by the regulating devices to keep the humidity at the proper point. The first portion of the eliminator baffle plates presents to the water merely a water covered surface, and contact with this is what removes the solid particles which may be in sus-

pension in the incoming air. The second portion of the plates is provided with vertical gutters which break the continuity of the water film and prevent its being blown from the farther edge of the plates and on into the fan and up into the building. The free moisture is removed by these gutters and runs into the solid matter removed from the air into a settling tank, beneath the washing chamber. Here there is provision for removing the accumulation of dirt, and then the water is pumped again to the spraying nozzles by a small brass centrifugal pump. The resistance to the air passage by the baffle plates is less than one-tenth of an inch water pressure, and hence is negligible. The design of the nozzles is unique, it may be added, because the water is atomized by



View Showing Face of Elminator, Buffalo Air Washer—Exhibited at Electrical Show, Montreal.

centrifugal force acquired by its rotative action acquired by the direction of its passage in leaving the nozzles. The setting tank is usually built in a concrete foundation for the washing chamber, it being found that this answers well and is both inexpensive and neat.

Another office that air washers are capable of filling during the summer is that of an air cooler. This is an important application for theatres in particular, and, of course, is used so in all installations during the warm weather. The Canadian Buffalo Forge Company has made installations and guaranteed that the final difference of temperature between the air and the water shall not exceed 20 per cent. of their initial difference in temperature.

Amongst the other exhibitors were: Adams-Bagnel Electric Co.; Aluminum Co.; American Conduit Co.; Babcock & Wilcox; Bell Telephone Co.; Canadian Pneumatic Tool Co.; Canadian Rand Co.; Dominion Electric Mfg. Co.; Dossert & Co.; Economical Electric Lamp Co.; Fibre Conduit Co.; John Forman; The Garth Co.; Jandus Electric Co.; Laurie & Lamb; Locke Insulator Co.; Marconi Wireless Telegraph Co.; Midland Electric Co.; Montreal Light, Heat & Power Co.; Montreal Steel Works; Munderloh & Co.; Canadian Sunbeam Lamp Co.; W. J. O'Leary & Co.; R. E. T. Pringle Co.; Phillips Electrical Works; Renolds-Dull Flasher Co.; Sayer Electric Co.; Stratton Engine Co.; Thomson & Co.; Wire & Cable Co.

In conjunction with the Exhibition were held the Canadian Electrical Convention and the Canadian Street Railway Convention, delegates to the both of which paid frequent visits to the Exhibition. The Exhibition closed on Friday at 11 p.m.

ONTARIO'S RICH MICA MINE.

At Sydenham, Ontario, sixteen miles from Kingston, is located the largest mica mine in the world. The product is mostly amber mica, with some silver amber, the highest quality mined. The mine is one mile from the upper end of Sydenham Lake, and the mica is transported in bulk from the mine by barge to the railroad st Sydenham, where it is shipped to Ottawa for trimming for the market. From Ottawa it is exported to the United States and other points. This valuable mine is owned and worked by Americans, and the output is almost entirely taken by one of the largest American electric companies.

CANADIAN MANUFACTURERS' ASSOCIATION.

The thirty-sixth annual convention of the Canadian Manufacturers' Association opened on Tuesday, September 24, with a large attendance. From east and west all the well-known men in industrial circles gathered at the King Edward Hotel, Toronto, and spent the week discussing papers relative to the progress of all manufacturing lines in Canada. This is the largest convention yet held, over six hundred members o'clock, among others, that of engines having registered.

The various sections met at ten and boilers. Mr. C. H. Waterous, the president of this division, was in the chair. The chief topic of discussion was a Boiler Inspection Act. At present there is a Dominion Act governing marine boilers, and absence of such a law was keenly felt in regard to the various other stationary and portable boilers. Another topic for discussion was the terms of selling engines and boilers, guarantees, cheque deposits and terms of payment. As it is now, some of the manufacturers quote f.o.b. cars and some erected, and steps were taken to remedy this.

Mr. Leonard, of London, was elected president of the division for the ensuing year and Wm. Inglis, vice-president. In our November number will appear a full account of the conference.

PERSONAL MENTION.

B. Welbourn, contract manager of the British Insulated & Helsby Cables Co., Prescott, Eng., has been making an extended tour through Canada, looking up trade conditions. He attended the Canadian Electrical Convention in Montreal.

J. E. Millen, of John Millen & Son, Montreal, is paying a visit this week to their Toronto branch. Owing to a steadily expanding trade in Toronto the firm has found it imperative to double the capacity of that branch.

G. W. Prouty, secretary of the Macallen Co., Boston, was a visitor at the electrical exhibition in Montreal. A. J. Dawson & Co., Montreal, who had an exhibit at the exhibition, are agents of the Macallen Co.

G. Walter Green, of Peterboro, has moved into his new machine shop. The new shop is on McDonnell St., directly opposite the old one, which will be used for foundry purposes.

Machinery at Canadian National Exhibition

Some Very Fine Exhibits, particularly in Machine Tools—New Machinery Hall Is Coming, but When?

As a compiled exhibition of Canada's products and resources, the Canadian National Exhibition is, without doubt, unsurpassed. At no other place nor time in Canada is there gathered together so varied a representation of the country's resources and the nation's products. And in most lines the showing is one that Canadians may be exceedingly proud of. The Exhibition, in later years, however, has only miserably represented one of the most important departments of Canadian industry, that of the growth and development of machinery. This regrettable fact can be immediately accounted for. It is not the result of lack of enterprise on the part of Canadian manufacturers. It is not on account of the lack of displayable Canadian machinery. It is, solely and directly, the result of the lack of an adequate building for exhibiting and of adequate means of handling this machinery.

Last year, it may be remembered, Canadian Machinery published, shortly after the Fair, the opinions of the heads of many of the leading machinery manufacturing firms in Canada regarding this matter. The opinions expressed were universal in confirming the statement expressed above. Several of the largest of these manufacturers, who do not now exhibit at the Exhibition, spoke of their willingness and eagerness to do so when adequate accommodation was provided.

This was the situation last year. It was hoped that a year would see some betterment of the situation, but matters seem to be in about the same position to-day. During the year a new Agricultural Building was erected, a new grand stand grew up out of the ashes of the old, and many other improvements were made. These were all needed, of course, but not more than a new Machinery Building.

Then, with the unprecedented success of the recent Exhibition, it was hoped that the long-neglected machinery department might be favored during the year to come. With this in view, a representative interviewed Dr. Orr, the Exhibition's manager, and one or two of the men who ought to know what is to be done. It was rather discouraging to find that the prevailing opinion is that the old Machinery Hall will have to do service for at least another year. Dr. Orr tells us, it is true, that an architect is working on provisional plans for a new structure, the work being carried forward on the basis of suggestions gathered from various sources, and that a new Machinery Hall is bound to come in time. But when is that to be? It may be another year; it may be two. At present there seems to be nothing definite concerning the matter. There is some excuse, of course, for the Exhibition management. The fire of last year crippled them somewhat in the matter of resources, and interfered materially with very excellent plans. This fact must be considered.

When the building does come it will, without doubt, be entirely worthy of the important department whose interests it will serve. Dr. Orr states that the plans now being prepared provide for a building several times the size of the present structure, to be placed, probably, further east than the present location. It will be designed to allow for the introduction of railway spurs into and through the building and will be fitted with electric and jib cranes and adequate means for handling the heaviest machinery. This is only what is required and has been expected.

This Year's Exhibits.

Notwithstanding all the drawbacks, inconveniences and lack of space, the exhibits of machinery at the Exhibition this year were surprisingly good, considering the circumstances, and the display, as a whole, was appreciably better than that of any previous year. This fact was particularly evident in regard to exhibits of machine tools. Several firms showed extensive lines of machines of both American and Canadian manufacture. One American firm went to the expense of bringing a large exhibit from Madison, Wis., and one enterprising Toronto firm carried on during the different days of the Exhibition a series of exhaustive tests of the tools it exhibited. Three producer gas plants were exhibited, only one of which, however, was in operation. The exhibit of motive power, in electrical and gas units, was very large and showed the recent development of this type of power. Gas power, in stationary, portable and marine engines, was particularly in evidence, some fifteen firms, showing different types of motors, having exhibits either in Machinery Hall, the Process Building, or on the grounds. The exhibits of electrical apparatus, always an interesting feature of the Fair, was larger than usual, and attracted a good deal of interest. Transmission machinery was well shown in several different exhibits and a couple of rotary engines created a good deal of interest.

The Dodge Mfg. Co.

An exhibit of various transmission devices was shown by the Dodge Mfg. Co., of Toronto, in the east end of Machinery Hall. The firm's well-known wood-split pulleys were shown in a variety of sizes, and also a new line, a split iron pulley, which combines the advantages of the split-pulley with the weight necessary for heavy work. A clutch connection was shown and also a system of rope drive transmission.

Canada Foundry Exhibit.

In their usual large space in Machinery Hall the Canada Foundry Company showed various products and machines which they manufacture. The working feature was a 500-gallon Underwriters' Pump, which supplied a miniature waterfall. Photographs were shown of large machinery and some of the large bridges built during the year, and surrounding the exhibit was a course of cast iron water pipe of various sizes.

In the Process Building the company exhibited a producer gas plant, a large Blackstone Oil Engine in operation, and two or three sizes of a simple and very powerful rotary pump.

Gisholt Machine Tool Co.

Considerable credit is due this American firm, who exhibited a very worthy representation of the lines of their manufacture.

Their exhibit included one of their well-known vertical mills, a tool grinder of special design, and a Gisholt lathe. This latter machine is worthy of special mention, being adapted for a surprisingly large variety of work on medium castings and forgings and for boring, turning and facing. It attracted a good deal of attention from machinery devotees.

Dominion Belting Co.

This well-known Hamilton company made an extensive showing of their Maple Leaf Belting. This brand, which the company claim to be the strongest and most durable driving belt on the market, is made from stitched cotton duck in all widths from 1½ to 60 inches, and in any length, without joints. It is lock-stitched with special cord, and is waterproofed by a special method. The company has recently made some extensive shipments to outside points, including Australia and South Africa.

H. W. Petrie's Exhibit.

Nothing could be of more interest to a practical machinist than machine tools in operation under actual working conditions. This is one reason why the exhibit of H. W. Petrie, in a prominent corner space at the west end of Machinery Hall, attracted more than usual attention. At specified hours during the Fair, tests were made of the various machines on exhibition. The results of several of these, with descriptions of

CANADIAN NATIONAL EXHIBITION—Exhibit of H. W. Petrie, Toronto.

the machines, follow herewith:

Just off the west aisle was placed an Improved Bickford Plain Radial Drill. This machine has a new drive, and is fitted with gear box. Under test, it drilled a 1½-inch hole 4½ inches deep in cast iron in 1.43 seconds, or an inch in 24 seconds.

At the rear of the exhibit stood a No. 2 Cincinnati Milling Machine. This tool turned out 45-10 pitch 28-tooth cast iron spiral gears of ½-inch face, in 11 minutes, the cutter running at 90 revolutions. The feed used was .063 per revolution of the spindle, and the work turned out was entirely free from chatter marks.

A 24-inch Improved Cincinnati Upright Drilling Machine, with tapping attachment, was drilling a ¾-inch hole 2 5-6 inches in cast iron in 39 seconds.

Alongside the north aisle was an 18-inch by 10-foot Lodge & Shipley 5-step Cone Standard Engine Lathe. This machine was reducing 3-inch diameter nickel steel at a periphial speed of 70 feet per minute, with a cut of ¼-inch and 3-16-inch feed.

A 15 by 48-inch Cincinnati Open Side Shaper was taking a cut of ¼-inch with ⅛-inch feed, without the slightest chatter, and this with the cutting done at the extreme end of the crossrail.

3 1¼-inch Simplex 4-Spindle Automatic Lathe, especially designed for all kinds of automatic work, was here making ¾x2½-inch wagon head cap screws at a rate of 30 per hour.

A No. 1 Universal Cincinnati Cutter and Tool Grinder was shown, grinding or milling cutters and doing other work.

These tests were made by stop-watch, under the direction of J. L. Bishop, an expert young machinist of Cincinnati, whom the Petrie Company brought from Cincinnati for this especial purpose.

Representing the firm's supply department, an attractive display of engineers' and millmen's supplies was made. A line of Pickering governors was exhibited, as was also a Vancouver 50-inch inserted tooth saw.

The exhibit was under the direction of Mr. Hallman, whose enthusiasm in explaining the features of the machinery and whose genial welcome to visitors aided materially in the success of the exhibit.

London Machine Tool Company.

One of the most interesting exhibits to machinery men who were interested in details, was that of the London Machine Tool Co., who had a promiuent space in the middle aisle of Machinery Hall.

Perhaps the most interesting feature of the exhibit was a 22-inch All-geared Lathe, a "made in Canada" product, being manufactured at the company's works at Hamilton and, as such, is a machine tool of which they may be justly proud. In this lathe the head consists of six gears of wide face and coarse pitch, working into positive clutches, giving four changes of speed in geometrical progression. With a three-speed countershaft, this gives twelve speeds. The bed is very heavy, of ample depth and width and particularly well braced. The racks, of accurately cut steel, are, excepting the long beds, in one piece.

The spindle of this lathe is a particular feature. It is manufactured from high carbon crucible steel, is first bored from solid stock, and finally put on a grinder and brought true to standard sizes. Then threads are chased on the nose, and bored to receive taper, bush and centre, which are very accurately ground and fitted by test. The end thrust is taken on ball bearings. This method of construction maintains the position of the spindle securely against the heaviest duty. The bearings are of bronze, carefully scraped and fitted.

The screw-cutting mechanism consists of a cone of gears into which rushes an idler gear, this being operated by a handle in front of the head. By means of this and inverting tumbler gears, screw-cutting feeds from one thread to 64 threads per inch, 54 changes altogether, may be obtained.

The tail stock is strongly built, and is provided with a set-over for turning tapers. Being of a cut-away type, it allows the compound rest to be set in a plain parallel to the bed. Two heavy bolts secure the tailstock against movement, and the tailstock spindle is especially ground and fitted. Altogether the lathe is planned to cover the largest range of work possible with such a machine. The fact that all gears are encased is an assurance of absolute safety in operation.

Another fine machine shown was one of the company's No. 2 cold cut-off saw, which is designed for cutting off bars, angles, eyepieces and other forms of steel, with the greatest rapidity. The saw is 26 inches in diameter, with ¾-inch face and runs in oil. The frame is built to stand highest duty and all equipment is of the highest class.

A couple of smaller engine lathes made by the Von Wyck Machine Tool Company, Cincinnati, for which the London Tool Company are the exclusive Canadian agents, was shown. One of these was a 15-inch machine, a particularly high-grade lathe, embracing all the most improved forms of design and construction. The headstock is particularly massive to provide for heavy work. The spindle is made from high-grade crucible steel with large bearings journaled in phosphor bronze. A feature of the carriage is the presence of "T" slots, allowing for numerous convenient operations. The chasing bial permits threads to be chased without stopping the lathe or reversing the head screw, the cross feeds are gradnated to one-thousandth of an inch, and the tailstock is designed so that the compound rest may swing at right angles.

The company manufacture only the finest line of machine tools at their works in Hamilton, and are selling agents in Canada for the Von Wyck Machine Tool Co., 15 in. lathes; the Kempsmith Mfg. Co., milling machines; Potter & Johnson Machine Co., automatic chucking machines and universal shapers; T. C. Dill Machine Co., Dill

CANADIAN NATIONAL EXHIBITION—Exhibit of London Machine Tool Co., Hamilton.

shapers; Murchey Machine & Tool Co., pipe threading machines and automatic taps and dies; Sibley Machine Tool Co., upright drills, and W. M. Sonnesson & Co., Sweden, shapers; with sales offices in the Traders Bank Building, Toronto.

The exhibit was in charge of Mr. A. E. Jubler, and was visited by other members of the firm from Hamilton, almost daily.

The A. R. Williams Machinery Co.

One of the most attractive exhibits in Machinery Hall was that of the A. R, Williams Machinery Company, Toronto. One reason for this is that machinery in operation always attracts attention. Another was that the exhibit was composed largely of machines and machine tools of Canadian manufacture and was thus an evidence of the growth Canada is making along these lines.

One of the largest machines shown was a 30-inch surface planer, of the Eclipse sectional roll type, manufactured by Major Harper & Son, of Whitby, who build a particularly high grade line of woodworking machinery. Samples of work done by the machine at one operation were shown, which were remarkably smooth and well finished.

A power pipe-cutting machine, built by McDougall & Co., Galt, was shown, which will cut from 1½ to 6 inch pipe either right or left hand. This machine is in use in several of the largest works in Canada.

Another Canadian machine was a Hall safety and automatic power press, which is made by J. B. Hall & Son, in Toronto.

An example of economic power was shown in the Hardill engine, which was running constantly. This engine, which is the invention of John Hardill, of Berlin, is of the tandem compressed type, and is operated by an ingenious mechanism with only one slide valve and steam chest, giving remarkable efficiency with great simplicity. The engine is handled by the A. R. Williams Company only.

Another "Made in Canada" machine shown was a bolt-threading and nut-tapping machine made by McGregor, Gourlay & Co., of Galt.

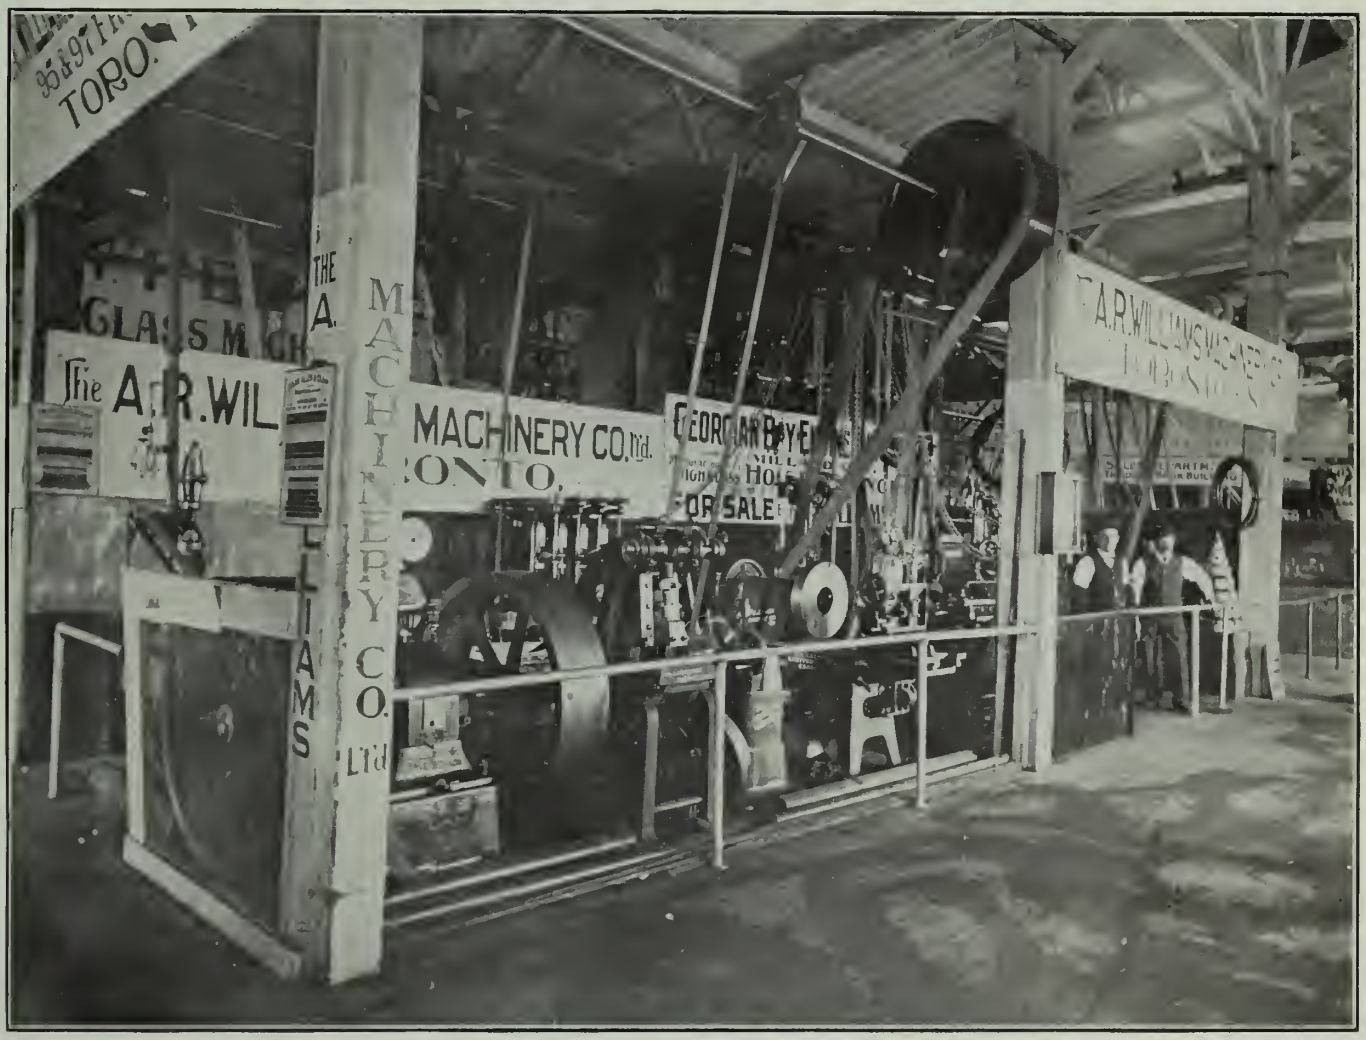
The A. R. Williams Company also represent some of the largest and best known American firms. Several fine machines of their manufacture were shown.

A power metal saw, built by Cochrane & Bly, of Rochester, one of the finest machines built to-day, cuts off a 3-inch steel shaft in 9 minutes, running at the slow speed, and in 5 minutes on the high speed. The machine has a capacity of 4 inches and turns out a beautifully-finished cut.

A 4-spindle multiple drill for the lighter classes of work, built by the Groton Machine Co., of Groton, N.Y., attracted a good deal of attention, as did also a 4-foot radial drill manufactured by the Fosdick Co., of Cincinnati.

A machine which has had large sale not only in Canada, but also in England, was a 22-inch sliding head power drill, with back gear, self feed and automatic stop. This is made by the W. F. & Jno. Barnes Co., of Rockford, Ill.

The firm's exhibit was under the direction of Mr. Cronk, who, with his assistants, was indefatigable in welcoming visitors and explaining the features of the various machines.



CANADIAN NATIONAL EXHIBITION—Exhibit of A. R. Williams Machinery Co., Toronto.

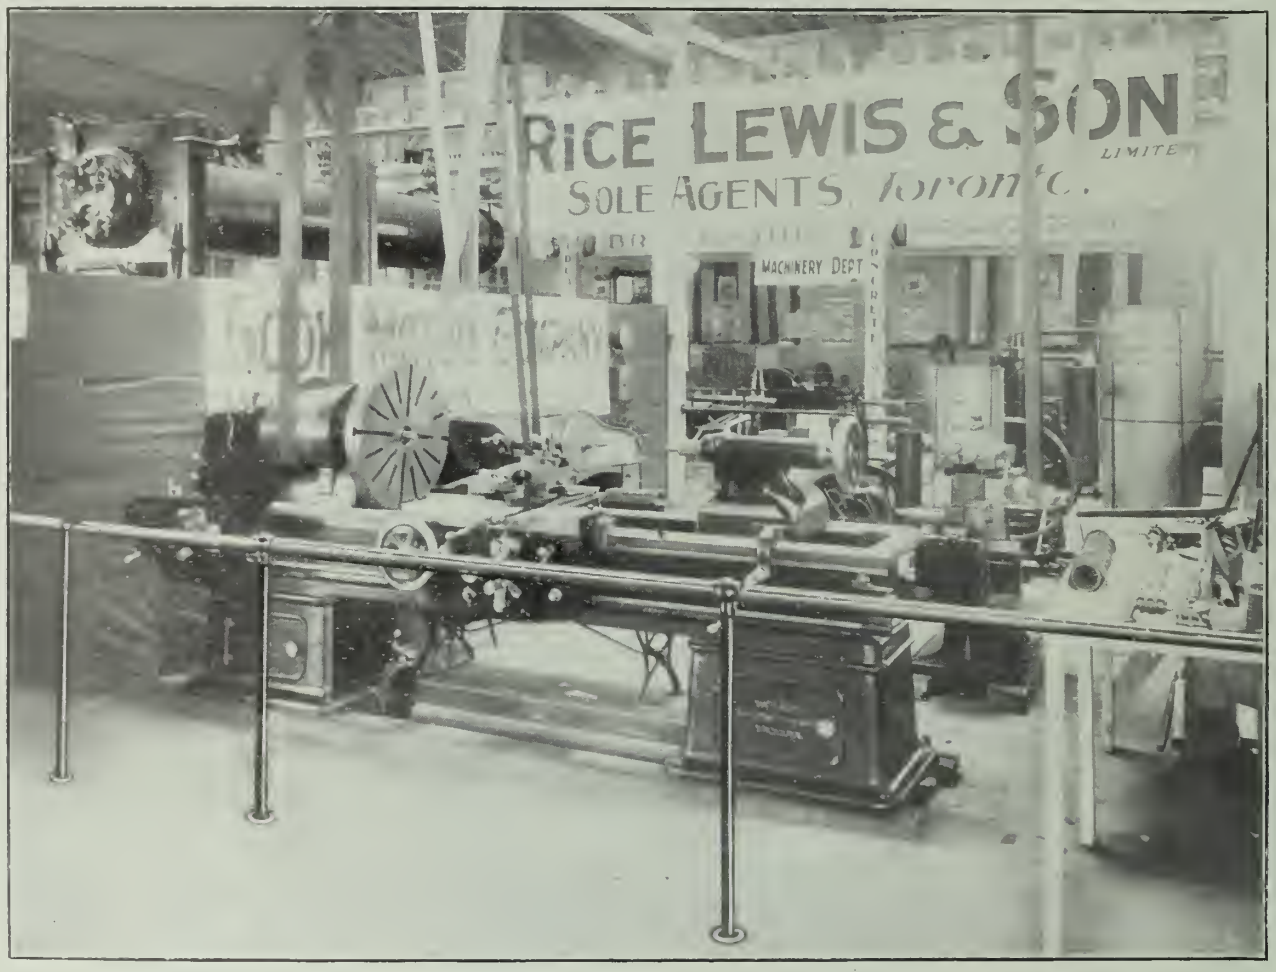
Exhibit of Rice Lewis & Son, Limited.

The Machinery Department of Rice Lewis & Son, Limited, Toronto, was very worthily represented by a large space in Machinery Hall. The department, but recently organized aims to supply the Canadian trade with the best grade of machinery manufactured by British and American firms in lines of machine tools, power, and transmission. The feature of the exhibit, without doubt, was a beautifully finished, heavy duty engine lathe, size 24 inches x 10 feet, manufactured by Schumacher & Boye, of Cincinnati, some of the special points of which are worthy of mention. The lathe is built with a three-step cone drive, giving a 4½-inch belt width for power, and at the same time giving 18 changes of speed without the introduction of a single extra gear in either counter shaft or head. It also possesses a special gear box, very rapid in operation and of broad range. A particularly broad and heavy carriage with double plate apron, provides a maximum of stiffness. These features on the lathe may be seen by reference to the accompanying photograph.

A Steptoe Shaper was also shown, built by the John Steptoe Shaper Co., of Cincinnati, who devote their entire attention to the production of high-grade, high-duty shapers.

A compact little emery stand, manufactured by Heinbuch Bros., of Stratford, Ont., was another tool exhibited, showing how such a tool can be improved by careful design and workmanship.

Motive power was represented by the Cook Motor Co., which was shown in two sizes, 3½ and 7 h.p., both running continuously during the Exhibition. The larger engine was belted to a generator which lighted a large illuminated sign above the booth. These engines are built both for lighting and general power purposes. For lighting they are arranged with a throttling governor for closer regulation, but for general power purposes they take a full explosion at all speeds and govern by patented governor of simple and effective design, so as not to reduce explosive power under varying speed. The 7 horse power shown was arranged for general power purposes, and, consequently, of coarser regulation, but Mr. Kellogg, who had charge of the exhibit, cut in a volt meter to show the close regulation of the engine, even under these conditions, and the absence of throw in the engine. There was no balance wheel on the dynamo to absorb fluctuations in the engine. The results under these conditions spoke well for the machine. The completeness of combustion was well demonstrated by the fact that these engines exhausted through their mufflers within the exhibit with absolutely no preceptible trace of gasoline vapor. These engines are built in vertical types only, up to 20-horse power, and are particularly well adapted for isolated lighting plants and for general power under varying constant speed. They won first award at a series of tests recently conducted at Ohio State University for economy in fuel consumption, and attracted a good deal of favorable comment at the Exhibition. The exhibit also included a display of "Conqueror" high-speed steel in fluted sections. The idea of the section is to reduce unnecessary weight and enable the mechanic to make most of his tools by grinding instead of forging. A remarkable saving in weight is effected in this manner.



CANADIAN NATIONAL EXHIBITION—Exhibit of Messrs. Rice Lewis & Son, Toronto.

The Canadian Fairbanks Co.

One of the largest and most complete exhibits in Machinery Hall was that of the Canadian Fairbanks Co., whose comprehensive display of various lines of the firm's extensive products, attracted a very great deal of attention.

The working features of the exhibit were particularly interesting. A vertical 6 h.p. Fairbanks Morse Gas Engine operating on kerosense, and ignited by magnetos, was belted to a Fairbanks Morse dynamo, which lighted 160 lamps in a large sign on the wall above the exhibit.

A 5 h.p. Horizontal Fairbanks Morse Gas Engine was driving a line shaft. This was fitted with a line of the firm's famous wood-split pulleys, and ran to the corner of the exhibit, where it was connected to another line of shafting by an interesting bit of mechanism, the Almond Right Angle Transmission. This coupling does away with troublesome bevel gearing and mule pulley stands, and is claimed to be a great economizer of power. The second line shaft was fitted with a line of steel pulleys and was connected in turn to another shaft at an angle of 30 degrees by a flexible coupling. This was certainly a novel and complete exhibit of transmission apparatus.

A 2 h.p. Frairbanks-Morse "Jack of All Trades" Gasoline Engine was in operation, as were also two of the firm's marine engines of the 2-cycle, 3-port type, a single cylinder of 4 h.p. and a double cylinder of 8 h.p. capacity.

A much-visited feature was a beautifully finished Fairbanks Personal Scale, fitted with Fan patent type registering beam, and with cast brass columns supporting beam. Visitors were weighed on this machine and their weight automatically registered on a small card.

A new cement testing apparatus, fitted with patent bearing, was shown, and a curious feature was a chair made up entirely of Fairbanks valves.

A new feature of the exhibit was a display of small tools made by Pratt & Whitney Dundas, for which the Canadian Fairbanks Co. have control of the entire Canadian business.

The Canadian Fairbanks Co. is showing surprising development. A large factory is now being erected at Sherbrooke, where a couple of hundred hands wil be employed early in the year in scale construction, and the branches of the company in the various Canadian cities are all doing largely increased business.

CANADIAN NATIONAL EXHIBITION—Exhibit of Canadian Fairbanks Co., Toronto.

Consolidated Electric Co.

The Consolidated Electric Co., of Toronto, showed a line of their King Edward motors, for both alternating and direct current, from ¼ to 25 h.p. One of their 25 h.p. multipolar generators was employed in lighting the exhibit. An interesting little machine shown was the company's new Monarch motor, which is designed especially for individual drive for printing machinery, and may be hung on the wall or ceiling.

Canadian Bearings, Limited.

A comprehensive exhibit of Wright's taper-roller bearings, which are claimed to be particularly suitable to line-shafting and for use in cranes and other bearings, where heavy weight and thrust is to be carried, was made by Canadian Bearings, Limited. They showed rollers which had been under heavy service for years with no perceptible sign of wear, and claim that the bearing will carry a thrust of 180,000 lbs.

Ontario Wind Engine & Pump Co.

The Ontario Wind Engine & Pump Co., in a large corner booth in the Implement Building, exhibited a line of Stickney gasoline engines, from 2 to 25 h.p. The features of the engine are a novel method of cooling, the exceedingly small water tank being an extension of the cylinder jacket, and improved methods of governing and ignition. They also showed the Erickson hot air pumping engine, the Canadian airmotor windmill and a line of iron pumps.

The T. & H. Electric Co.

One of the best-arranged and most complete exhibits in Machinery Hall was that of the Toronto & Hamilton Electric Co., in a corner space on the north aisle. A couple of the larger machines shown were 10 and 12½ k.w. direct current generators, a line which the company build in all sizes, from 1 k.w. up. A line of beautifully-finished induction motors was shown. These were built for various frequencies, and in 1, 2 and 3 phase type. The company make a specialty of motors designed particularly for direct connection to steam, water, gas and other prime movers, and are able to supply these in any size and for both direct and alternating current, and from 1 k.w. up. A line of beautifully-finished induction motors was shown from ½ to 25 h.p. These were of 1, 2 and 3 phase type, and built for various frequencies.

The company make a specialty of building generators for belting and direct connection to steam, water, gas and gasoline or other prime movers. One of these machines was shown running, fitted especially for belting to a gas or gasoline engine.

An interesting feature was a selection switch for disconnecting high potential lines from transformers when repairs or changes in the line are required. This was designed for 10,000 volts, 600 amps.

A very compact little outfit shown was a motor-generator set, designed for charging storage batteries. This consisted of an induction motor, single-phase type, directly connected to a direct-current generator.

The switchboard at the rear of the exhibit was very complete as to detail, and the display also included medals and diplomas awarded the company at the Exposition in previous years.

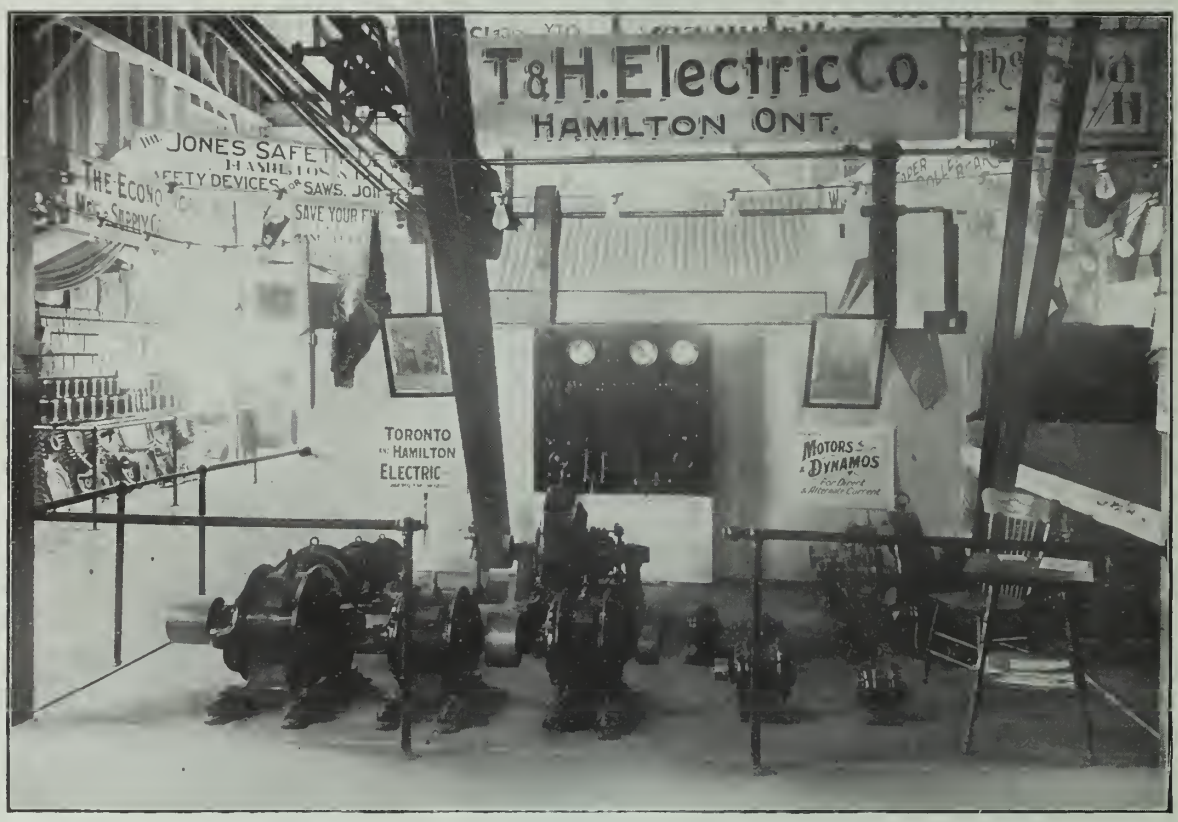
Borden-Canadian Co.

This exhibit was at the west end of Machinery Hall, where threading machines, both power and hand, were shown.

The main feature was a new Beaver die stock, the machine illustrating the new way of threading pipe. This stock threads pipe from 1 to 2 inches without changing the dies, which is a revolution in pipe threading, doing away with the annoyance and time required when changing from one size pipe to another. The ease of operation of this machine is striking. A man with one hand is able to thread a 2-inch pipe without any difficulty, whereas under the old system it really called for the strength of two men. The reason of this working easily is that the dies recede as the stock commences to advance on the pipe, thus, the further the operation is proceeded with the easier it works.

Evans Rotary Engine.

A new exhibit which attracted considerable attention was the Evans Rotary Engine. Placed on a small platform, not even bolted to the flooring, was a small cylinder about 18 inches in diameter and about 2 feet long. This, with a governor and steam pipe connection furnished 25 h.p. to drive a 10 k.w. generator, which lighted a large sign. Mr. Evans, of New York, the inventor of the engine, was present for a couple of days at the Fair. He claims that the engine will furnish the same amount of power on half the amount of steam required by a reciprocating or turbine engine. A number of these engines were sold during the Fair, and the company, which has only been established in Canada since June, received a good deal of encouragement.



CANADIAN NATIONAL EXHIBITION—Electrical Exhibit of the T. & H. Electrical Co., Hamilton.

The Jones & Moore Co.

In the middle aisle of Machinery Hall the Jones & Moore Electric Co., Toronto, had a very complete exhibit, showing lines of the machines they manufacture. The floor space was well covered with different sizes of their motors, both direct and alternating type, in the former from 1 to 80, and the latter from 1 to 60 h.p. In the rear of the exhibit two large direct current generators of

the firm's standard type were running from the line of shafting above. These supplied current to several of the other exhibits, and lighted a string of varicolored lamps around the company's exhibit.

The Stryeker Pattern Works.

The earlier processes of the making of a machine are generally unknown and scarcely thought of by the general public. On this account the exhibit of the Stryeker Pattern Works, on the north side of the Process Building, was a revelation to most visitors, and it was usually surrounded by a crowd who eagerly watched the operations of pattern making. In the exhibit several of the company's employes were doing the regular lines of work turned out in the factory at 87 Jarvis Street, Toronto. To facilitate this the exhibit was equipped with a lathe for wood turning, a band saw, circular saw, trimmer, and, of course, a full outfit of pattern-makers' tools. Around the booth also were finished patterns of the company's manufacture, including propellers, sprocket wheels, and even coils for chain heaters. The largest pattern exhibited was an electric motor case, this class of work being a specialty with the firm, as well as patterns for dynamos, gas engines, stoves, etc.

The company has a separate metal department, specially equipped for turning out patterns in brass, white metal and iron. This, with their wood pattern department, covers every range of demand in the pattern line. The firm employ the best class of labor to be found in this line, use only the best material, and, by insisting on high grade work, have built up an extensive local and Canadian trade during their three years of existence.

CANADIAN NATIONAL EXHIBITION—Exhibit of Stryeker Pattern Works, Toronto.

The Canadian Westinghouse Co.

The Canadian Westinghouse Company had an attractive exhibit in the Process Building. Their installation included a motor-generator set, a type C, C.L. induction motor, driving a type S generator, this in turn driving a line of direct current motors. A line of induction motors were wired to a large starting panel, 3,300 volts, 200 amps, and one of the firm's modern switchboards controlled the direct current motors. In the other department of the exhibit a line of Nernst lamps for office and outside fixtures was shown, and hanging in the dome of the building, just above the exhibit, was a Nernst lamp of 30 gloires, the largest one of its kind ever made, which lighted in a notable way that section of the building.

Galt Electric Co.

A big winking sign on the west side of the Process Building made known the whereabouts of the Galt Electric Co., and incidentally made an exceedingly good advertisement. The company showed a couple of complete lighting plants of small capacity, for hotel, club and store lighting, a line in which they specialize. They manufacture these isolated plants in standard sizes, with a capacity of from 20 to 100 lamps of 16 c.p., and are finding ready sale for these outfits.

Gould, Shapley & Muir Co.'s Exhibit.

The Gould, Shapley & Muir Co., of Brantford, exhibited a line of their Ideal Gasoline Engines, from 4 to 25 h.p., also pumping and sawing outfits, concrete mixers, feed cutters and windmills.

The I. E. Schantz Co.

In a commodious space on the north side of Machinery Hall an exhibit of power pipe-threading machinery attracted, and was worthy of, a good deal of attention. Three power machines were shown, a No. 6, with capacity from 2½ to 6 inch pipe; a No. 4, which will cut from 1 to 4 inch, and a No. 2, cutting from 1 to 2 inch. All three machines were in operation.

The largest machine, No. 6, which is of new design, and numerous improvements which make it superior to anything of the kind previously built, is, by the way, described in detail, with a photograph, on another page of this issue.

In connection with this machine, Mr. Schantz, who was meeting the trade at the booth during the Fair, tells an interesting story. "Only a short time ago," says Mr. Schantz, "this machine did not exist. The design was but recently finished, and the patterns were made, castings completed, and the parts put together only a short time before the Exhibition." The facility with which this was done tells another story about the efficiency of the company's plant in Berlin. When assembled and tested, the big machine proved so surprisingly satisfactory that it was carried down bodily to the Exhibition and while there excited a good deal of favorable comment from machinery men. The machine cuts a perfect thread on a six-inch pipe at one cutting, whether the dies be new or worn. It will also cut smaller sizes of pipe down to 2½ inches. The machine has weight and power enough to do the heaviest work satisfactorily, and produces no wavy thread, even under the hardest conditions. The first thread cut, a section on a big 6-inch pipe, which was run through the machine immediately after it was assembled, was on exhibition.

The smaller machines were built after the same design and with practically the same features. The fact that several of these were sold during the two weeks of the Fair is an evidence of the impressiveness of the exhibit.

The Schantz Co. have already built up a large business in pipe-threading machinery, of which they make a specialty, and this new type of machine should bring many orders to their factory.

Beaver Marine Engines.

A line of Beaver marine engines was exhibited by the Sherman-Cooper Co., of Toronto. An interesting feature was a section of one of their single-cylinder engines, cut down to show the fine interior finish, the excellence of the casting and the positive oiling device used in their engines. The wall at the rear of the exhibit was hung with a display of propellers and small boat fittings.

CANADIAN NATIONAL EXHIBITION—Exhibit of I. E. Shantz, Berlin, Ont.

The James Morrison Brass Exhibit.

The James Morrison Brass Mfg. Co. had their usual fine exhibit of their products. This included a line of very fine lighting fixtures, engineers' supplies, including extensive lines of injectors, brass and cast iron valves, steam gauges, engine indicators, oil cups, water gauges and locomotive bells and whistles.

N. J. Holden Company.

The only exhibit of pneumatic tools at the Fair was made by the N. J. Holden Company, of Toronto and Montreal. On a table in the front of their exhibit, on the south side of Machinery Hall, was a line of these tools, including pneumatic hammers and rammers, electric drills and mining tools. One of the most interesting of these was a magnetic "Old Man," which, wired to a lighting circuit, clamped itself instantly to a steel plate or any surface to be handled. The tool was exceedingly simple, being provided with a powerful electro-magnet in the base, which did the work. Many of the tools in the exhibit were made by the Chicago Pneumatic Tool Co., of which the N. J. Holden Co. are the Canadian representatives. This company also manufacture air compressors in 100 sizes and various styles, of which many are placed in Canada. A large air-compressing plant of the company's standard type was sold, by the way, during the Fair, to Norton Bros., of Campbellford, for use in their new bridge works there. The company also make a line of rock drills and all sizes of stonecutters' tools.

The N. J. Holden Company also represent the McCord Co., of Chicago, who manufacture axle boxes for railway cars, spring dampeners, and bumping posts. Along with other lines of railway supplies they handle Priest Snow Flanges, the McKim Gasket, Fewing's Car and Engine Replacer, and the Gilmour-Brown Emergency Knuckle. The firm handle a full line of the cold metal saws made by the Quincy, Manchester Sargent Company, of New York. To complete their line of railway supplies, the N. J. Holden Company carry the goods of the Pantasote Company, and are their Canadian agents. This company manufacture Pantasote, the substitute for leather which has had such wide usage in recent years, and also an exceedingly fine line of curtain goods, car blinds, etc.

CANADIAN NATIONAL EXHIBITION—Exhibit of the N. J. Holden Co., Montreal.

Chapman Ball Bearings.

The visitors interested in frictionless transmission kept Mr. C. M. Murry and a staff of able assistants busy from morning till night showing the good points of the Chapman Double Ball Bearings and the many machines in which they may be economically used. A large sign in the centre showed where the exhibit was, and on it was a cut of the now well-known Chapman double ball bearings. An interesting test was carried on and showed conclusively the superiority of Chapman's double ball bearings over the ordinary kind. Besides a wheel which had seen a long, active service and still ran as if new, there were exhibited ball bearings for almost every industrial use. A Sheldon blower was equipped with ball bearings, and blew skyward streamers of red, white and blue, helping to make the exhibit quite an attractive one.

The Smart-Turner Company.

The Smart-Turner Company, of Hamilton, evidently believe in doing one thing and doing that well. Their exhibit was made up of lines of the various styles of pumps manufactured in their works. These included a full line of boiler feed pumps, a heating system for boiler feeds, and a large centrifugal pump in operation. This pump was employed in raising sludge, and is specially adapted for pumping sewage and heavy material.

Nicholls Bros.

In the east end of the Implement Building, Nicholls Bros. exhibited a full line of ignition outfits, including magnetos, spark coils and spark plugs. They make a specialty of the "Syntic" ignition system, and showed a system in operation. Their display of small ammeters and voltmeters for small electric plants, was also attractive.

The Automatic in Manufacturing

Comparisons Between Setting Up Automatic and Hand-Screw Machines.

By J. P. Brophy, Cleveland Automatic Machine Co.

The operations of putting in chuck and shell and bar stock, are, of course, the same in either case. Also, this is so in regard to placing and adjusting the tools in turret and on cross slide. Now comes the difference: on the hand machine there are adjustable stops to be set for each tool in turret and on cross slide; on the automatic machine we have adjustable cams to set, which should take the operator no longer to set than the stops on the hand machine. As far as the above argument goes, both machines stand about equal, but we have yet the most important advantage in favor of the automatic, which is that the operator of automatics sets one of his machines while all the others in his charge are running, and, assuming that he has six machines in his care, only one-sixth of his output is stopped temporarily; while, in the case of the hand machine operator, his entire output is stopped while setting his machine, and there are more reasons why the setting-up features of the automatic screw machine have been improved, to the extent that it is simpler and easier to set than a hand machine. The numbering of regulating drum, cross slide drum and turret holes makes it possible to make out a test card for each set of tools to be used by the operator in changing from one piece of work to another. The test card enables a man with very little experience to place the cams and tools in their proper working positions, and in a shorter time than would be possible to set up a hand machine.

In turning out parts, the automatic leads all other ways. This shows up especially in the large diameter parts, such as transmission gears, ball bearings, roller bearings, pistons, thrust washers, bushings, equalizing gears, etc., either castings, forgings, or bar stock; also, for parts of all kinds for the following: typewriters, sewing machines cash registers, adding machines, agricultural machinery, railroads, tool builders, elevator, electrical, wood working and textile machinery; in fact, in manufacturing parts of all descriptions the automatic can be used to advantage. In using automatic machines on any class of work, the element that we call "human nature" in the operators, by which we mean all things which come up distracting the attention of the operator, decreasing the actual working time of the tools, and, consequently, the output is all done away with, for the obvious reason that the automatic machine is in active operation continually, losing no time from actual cutting.

Manufacturers who are wide-awake are steadily coming to the front in the use of labor-saving machinery However in the turning out of the larger parts, the manufacturer who has not installed automatics has to depend on lathe work, or hand machines, and one of the most expensive operations in the factory to-day is lathe work. An automatic operated by a medium-priced man can do high-class, accurate work, that on a lathe would require a fine mechanic receiving the highest pay, and the automatic operator can care for from four to eight machines. The manufacturer depending on such methods is not only losing money, but is making the cost of his product so high that he is not in a position to compete with the wide-awake man who enjoys the saving he is able to make by taking advantage of automatics. He is also losing money by not having a machine that will overcome the great difficulty of men working on hand machines being absent when the parts are most needed, resulting, possibly, in the closing down of some parts of the factory, which means additional expense to the company. It is very easy for a busy manufacturer, whose time and energy is continually being expended in keeping his design and construction up to the latest ideas and improvements, to keep putting into the future the installation of automatic machines for his work, even though he is dimly conscious that he is paying out money for wages, which is unnecessry and the reason that he has been so passive in this respect is because he has no adequate idea of the unbelievable difference in the labor cost of work produced on the automatic as against the machines spoken of above. Of course, automatic machines have been used on small work for years, but the purpose of this article is to bring to the attention of users of engine lathes, turret lathes and hand screw machines, the saving to be effected by these money-saving machines, which are especially adapted to finishing parts, large and small, up to 6 inches in diameter.

I want here to get the particular attention of shop superintendents in regard to duplicate parts. I venture to say that every superintendent who makes his own parts has been time and again exasperated almost to the bursting point by the continual habit of lathe hands getting things too long or too short, or too small, or too large. Now, we come to one of the most essential characteristics of the automatic machine. You can rest assured that the parts will be exactly alike in size and shape. This brings up another thought along this line. Some people claim that accurately finished work cannot be produced on an automatic machine, and that all the work has to be gone over on the lathe. This is not the case, as the machines are made to finish the work to size. The modern, large automatic machine is built rigid and heavy wherever great strain comes and the forming tools come up solid against a stop, giving exact size. Also, there is a sufficient volume of oil flowing on the tools while working to keep same thoroughly lubricated and the work cool, which tends towards accuracy. Nothing is left to the eye sight or feel of the operator to obtain the size. The machine takes care of that; consequently the "human element" is no longer there to be contended with, and one of your greatest difficulties eliminated. There can be no mistake on this point since the tools travel to proper distances with positive cams and adjustable stops. Accuracy must be the result after the first piece has been made to gauge. You may continue till parts are completed and the variations will be found within the required limit.

The regularity and steadiness and power of the tool feed allows of long-continued working of the tools without attention. The feed of the tools is not forced at one moment and light at the next, as is often the case of the hand machine, but is always advancing into the work at the rate it should be. In this way we obtain a great output with the minimum attention being paid to the tools. Tools on automatic machines require less attention than hand machines, because they are self-operated and do not have to contend with the different temperaments of man. The automatic works the same on "blue Monday" as on Saturday, which means a great saving on tools. Hand machine tools are very often broken by the operator conveying the tool to the part to be machined, and jamming into it, which is almost sure to result in the work being spoiled, or a broken tool. The automatic is positive in its idle movements, and can be relied upon to carry each tool direct to the part to be worked without losing any time or endangering the tools. After the tool feed has been properly adjusted on the automatic, each tool will be subject to the same strain, and will invariably take the same time to remove the stock, which will result in the tools lasting longer

and will produce more accurate work than would be possible on a hand machine. Also, the great volume of oil continually pouring over the tools and the work, and through the internal oil tube of drills, counterbores and boring tools, adds greatly to the length of the time the cutting tools will stand up. If an automatic machine were to be set up to produce in one day the exact same number and kind of pieces that it would be possible to produce on a hand machine in the same time, the automatic machine would run slower, the feed of the cutting tools easier, and the tools on the automatic would stand up without re-grinding very much longer than on a hand machine. All this on account of the ceasless "hammering away" every minute of the day, which is characteristic of automatic machines.

In the race to keep up with the procession, the installation of labor-saving machinery has been neglected. In order to turn out work rapidly and smoothly, it is necessary to have parts made so that they will go together without extra labor, which has the beneficial result of less cost to assemble, and far greater output. A considerable part of the time spent in assembling, under the present conditions, is due to variation of sizes of the parts, necessitating extra labor before it is possible to put the parts together. Automatic machines will overcome this condition, and the manufacturer who is first to equip his factory with modern methods of producing the parts which he must have, is destined to have the greatest hold on the industry.

It is only within the last few years that large bars could be had without long delay. Now it is carried in stock and can be had on short notice. This was formerly one of the handicaps of the large automatic machine. It was thought that an automatic machine, to handle large bars, would be a ponderous affair, too clumsy and slow to be of much use and, also, calling for too large an outlay of money to instal them. The large automatics of to-day, however, after the past few years of hard application and experiment, are models of compactness and simplicity. They are not cumbersome, and you would not even call them large, when you consider the size of the work they produce. To come to the point in this argument, increasing the capacity of the machine does not increase the floor space very much; though, of course, it increased the weight very rapidly as the large machines are made exceedingly rigid to withstand the heavy strain. The mechanism for obtaining the automatic movements is not clumsy and awkward, but remains practically the same size as the same mechanism on smaller machines. Thus, the movements are all quick, light and easy. These large machines are no harder to operate than smaller ones, and an operator can take care of just as many as he can of the smaller sizes. Consider for a moment what this means. Take, for example, the steel sliding gear of a transmission for an automobile, which has taken a lathe hand four hours to make, representing a labor cost of about $1.10 to $1.20. Now, put this same job on an automatic machine and it would take the machine approximately one hour to make the piece. The operator is running, say, four machines, which would be a low estimate; the price paid the operator for producing one piece would be from six to seven cents, against the total of $1.10 to $1.20 paid to the lathe hand.

In a large automatic room it is only necessary to have one first-class man to look after the grinding and setting of tools, and all the other help is of the cheapest variety.

Viewed from the state of perfection of automatics a few years ago the class of work done to-day was an impossibility, but the thought of automatic builders has kept pace with the improvements in other lines, and has resulted in the present high state of development which automatics have reached.

AMONG THE SOCIETIES

CANADIAN ELECTRICAL CONVENTION.

The annual convention of the Canadian Electrical Association was held in Montreal on Sept. 11, 12 and 13. The more interesting features of the convention were the President's address on opening day, a visit of delegates as a body to the Electrical Exhibition, question box discussion, a theatre party, visits to Blue Bonnets Race Track and Dominion Park.

Opening Session.

The President, R. G. Black, opened the convention by an interesting address on the importance of producers of electric energy extending their markets in order to make any profit at present rates. During the opening day a handsome gold watch was presented by the members to Mr. Mortimer, who, it was stated, had taken an active part in the work of the society ever since it was started, sixteen years ago—for many years its secretary.

The report of the Secretary-Treasurer, T. S. Young, showed that the society was flourishing, the membership being 320, and there being a good sum to the society's credit in the bank.

On Thursday took place the election of officers for the ensuing year. The following is the result: President, R. S. Kelsch, Montreal; First Vice-President, W. N. Ryerson, Niagara Falls; Second Vice-President, R. M. Wilson, Montreal; Secretary-Treasurer, T. S. Young, Toronto. The Management Committee is composed of A. A. Dion, Ottawa; B. F. Reesor, Lindsay; C. B. Hunt, London; J. M. Robertson, Montreal; J. J. Wright, Toronto; J. G. Glaseo, Hamilton; R. B. Black, Toronto; W. Williams, Sarnia; H. O. Fisk, Peterboro; J. W. Purcell, Walkerville.

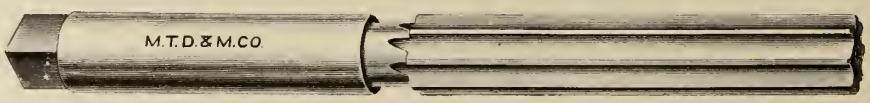
Papers and Addresses.

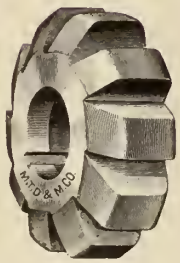
President's address; A. B. Lambe, "Electric Heating and Cooking Devices"; M. A. Sammett, "Trials of the Operating Man"; B. T. McCormick, "Three Wire Generators"; Clarence E. Delafield, "High Tension Insulators from an Engineering and Commercial Standpoint"; A. E. Fleming, "The Value of the Nernot Lamp to the Central Station"; J. M. Robertson, "Incandescent Lamps"; John Murphy, "Frazil and Anchor Ice"; R. M. Wilson, "The Load Factor"; G. P. Cole, "Modern Lighting Transformers"; G. H. Montgomery, "The Responsibility of Electric Companies for Accidents."

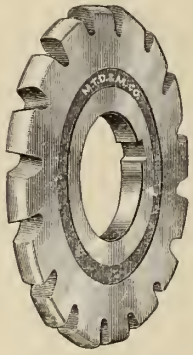
The papers read by John Murphy and G. H. Montgomery were especially interesting and instructive. It was left to the Management Committee to name the next place of convening, and to the Secretary to send formal votes of thanks to all who had aided in the entertainment of the delegates and to those who had read papers at the convention. The Montreal Street Railway were very kind in placing special cars at the disposal of the delegates to attend the horse races and see the city. The session closed at 12.30 on Friday afternoon. Allis - Chalmers - Bullock, Limited, had issued and distributed among the delegates a very nicely printed programme of the convention.

"MORSE" TOOLS

Drills, Reamers, Cutters, Chucks, Taps, Dies, Machines, Machinists' Tools, Arbors, Counterbores, Countersinks, Gauges, Mandrels, Mills, Screw Plates, Sleeves, Sockets, Taper Pins, Wrenches.







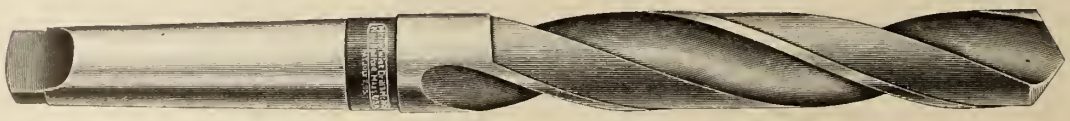
A GOOD MECHANIC wants good tools.

GOOD TOOLS are made of the best material.

The BEST MATERIAL is given to capable workmen.

CAPABLE WORKMEN make honest tools.

Therefore MORSE TOOLS GIVE SATISFACTION.



Morse Twist Drill and Machine Co.

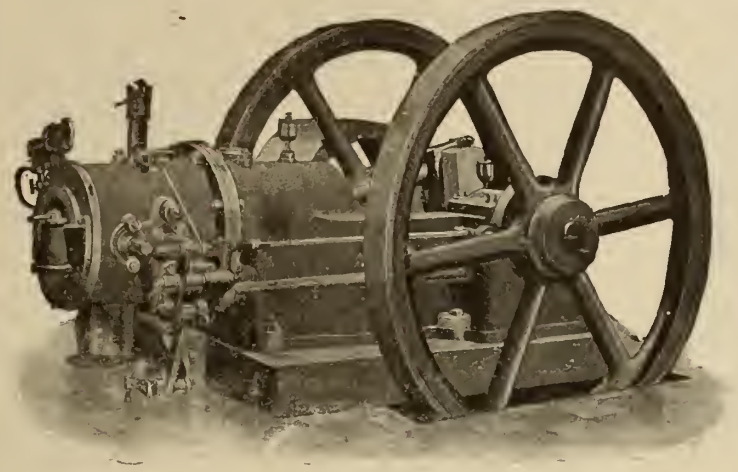
NO ASHES TO BURN



IF YOU USE A

"PREMIER" GAS ENGINE

and when installed with a **Canada Gas Producer** it will save more coal than burning ashes.

LET US TELL YOU ABOUT IT.

CANADA FOUNDRY COMPANY, Limited

Head Office and Works: TORONTO, ONT.

District Offices: Montreal Halifax Ottawa Winnipeg Vancouver Rossland

Electrical Power Plants a Specialty

SUPPLIERS OF:

Hydraulic and Pumping Plants
Electrical Generators
Electrical Motors
Arc Lamps, ordinary or flame
Cables, high and low tension
(Specialty in Paper Insulation)
Switchboards
High-Tension Switch Gear
Supply Meters
Transformers
High-Efficiency Incandescent Lamps
Gas Engines and Producer Plants

Send us your enquiries, nothing too large or too small.

Wm. & J. G. Greey, 2 Church Street, **Toronto**

Manufacturers Flour, Oatmeal, Cereal Machinery, Grinding, Blending and Sifting Appliances, Chilled Iron Rolls and Rolling Mills, Paint and Ink Machinery, Trucks, Power Transmission and Elevating Apparatus.

MANUFACTURERS AND MANUFACTURERS' AGENTS.

It will pay you to watch our condensed column each month. There are many money-making propositions brought to your attention here. You may find just what you are looking for.

RATES

One insertion—25c. for 20 words; 1c. a word for each additional word.

Yearly rate $2.50 for twenty words or less, 10c a word for each additional word.

The above does not apply to notices under the head of "Machinery Wanted." These notices are inserted free for subscribers.

BUSINESS CHANCE.

FOUNDRY FOR SALE—In a thriving Ontario town of five thousand inhabitants; is a going concern, employing from ten to fifteen hands, and does a general foundry business; no opposition within ten miles, and there are numerous orders now on hand; owing to a dissolution of the partnership the business must be sold at once. Apply Box 45, CANADIAN MACHINERY, Toronto.

FOR SALE.

BELTING, RUBBER, CANVAS AND LEATHER, Hose, Packing, Blacksmith's and Mill Supplies at lowest prices. N. Smith, 138 York Street, Toronto. (2tf)

AUTOMATIC stocker, with fan and engine complete, in good running order; snap; reason for selling, compelled to burn shavings. Apply A. J. H. Eckardt, National Casket Co., 107 Niagara St., Toronto. (9)

GASOLINE engine, 12 h.p., good as new; price, $275. Krug & Crosley, Hamilton. (9)

FOR SALE—The Canadian patent rights on a valveless pneumatic hammer, proved by actual test to be superior to any hammer at present on the market; an arrangement can be made to manufacture same on royalty for Canadian market. Apply Box 39C, CANADIAN MACHINERY, Toronto. (9)

SITUATION VACANT.

WANTED—Young man well experienced in machinery supply business able to sell and knowing thoroughly all requirements of the trade. Salary, commission and share of profits. Apply Box 32, CANADIAN MACHINERY, Toronto.

WANTED AT ONCE—Superintendent and mechanical engineer for machine works manufacturing gasoline engines and general machine work; one familar with modern methods, capable of making estimates, drawings and producing work at minimum cost; give full particulars of qualifications, experience, age, nationality and salary. Apply to Brandon Machine Works Co., Ltd., Brandon, Man. [9]

SITUATIONS WANTED.

ADVERTISER, shortly emigrating, seeks position as correspondence clerk and accountant. Well up in all details of engineering and allied business; ledger balancing, shorthand and typewriting; excellent references. Lister, Ipswich Road, Ardleigh, Colchester, Eng.

A Firm of Chemical Engineers

are requiring first-class agents in the large cities of Canada. Apply to W. J. Fraser & Co., Ltd., Chemical Engineers, 98 Commercial Road East London, England. [11]

We should have your business.

If prompt delivery, reasonable prices and best of workmanship appeal to you, we should have your pattern orders.

CANADIAN MACHINERY

Montreal Toronto Winnipeg

THE CANADIAN TURBINE WATER WHEEL

We have not expanded the discharge of our turbines, as we find the results given by our combined impact and reaction runner to be vastly superior to those obtained from turbines of the expanded discharge type. Do not sacrifice your water power. We can save you 20 to 30 per cent. of your water and at the same time give you a much more satisfactory drive.

DO YOU USE **PLUMBAGO** IN YOUR FOUNDRY?

If you do, we would like to submit a sample of our

Columbia Dry Sand and Loam Facing

which we are now marketing, and which will cost you from 200 to 300 per cent less than your Plumbago, yet gives as good, if not better, results.

It can be used on the heaviest kinds of cores, dry sand, loam and skin dry work. The sample will cost you nothing, as we know that a trial will convince you of its economy and plainly show its many advantages; therefore we will be willing to stand this expense, if you will give it a fair test.

TOOL ROOM ECONOMY :—

The Use of Diamo-Carbo Emery Wheel Dressers.

The ***Diamo-Carbo Dresser*** is the only satisfactory substitute for the black diamomd. Permits you to true and shape your wheels just the same as with the more expensive device, and s adapted for use on all tool grinding wheels. The hardest abrasive known; wears indefinitely; and cannot get lost or broken and will not injure the edges of the most delicate wheels.

Made in three lengths: 8", 10" and 12" respectively.

Prices: $3.00, $3.50 and $4.00

Tell us which length is best suited for your needs, and let us send a Dresser on ten days' trial. Booklet and testimonials for the asking.

3 to 5 ton style.
Round's Spur-Geared Blocks are made 1-4 ton to 20 ton.

ROUND'S SPUR-GEARED BLOCKS

HIGHEST SPEED **HIGHEST EFFICIENCY**

In Round's Spur-Geared Blocks you obtain 80% of the applied power in useful work, whereas in the average hoist you obtain only about 25%.

This is the highest efficiency obtainable in the present chain block line. It works easier, faster and is safer than any other make or type of hoist.

The load is sustained by a separate automatic brake, which takes up its own wear and is safe and positive.

We have placed a large number of these chain blocks, and they have given entire satisfaction.

ENGINEERING:

AN ILLUSTRATED WEEKLY JOURNAL

Edited by WILLIAM H. MAW and B. ALFRED RAWORTH

PRICE SIXPENCE.

"ENGINEERING," besides a great variety of Illustrated Articles relating to Civil, Mechanical, Electrical and Military Engineering and Notes of General Professioual Interest, devotes a considerable space in each issue to the illustration and description of all matters connected with the PRACTICAL APPLICATION OF PHYSICAL SCIENCE, and with its Wide and Influential Circulation in all parts of the world, this Journal is an

UNRIVALLED MEDIUM FOR ADVERTISEMENTS

SPECIAL NOTICE TO CANADIAN SUBSCRIBERS—The Publisher of ENGINEERING desires to call attention to the important reduction in the subscriptions for Canada. Owing to the new arrangements with the Dominion Post Office, the postage rate for newspapers is now 1d. per pound, and the annual subscriptions for ENGINEERING posted direct to Canada will, until further notice, be

Thin Paper Copies - - - - - - £1 11 6
Thick " - - - - - - £1 16 0

Subscribers residing abroad are strongly recommended to order copies on thick paper, as the illustrations are necessarily very much less effective in the thin paper edition, and to remit, when possible, by Post Office Order made payable at Bedford Street, Strand, London, W.C. When Foreign Subscriptions are so forwarded, advice should be sent to the Publisher.

Foreign and Colonial Subscribers receiving Incomplete Copies through Newsagents are requested to communicate the fact to the Publisher, together with the Agent's Name and Address.

Cheques should be crossed "Union of London and Smiths Bank, Limited, Charing Cross Branch."

All accounts are payable to "ENGINEERING, LIMITED."

ADVERTISEMENTS.

"I've Now More Than I Can Read"

¶ Yes, Mr. Business Man, we are well aware you have not time to read all the publications that come your way each month.

¶ But do you really devote the time you should to reading? Do you get the timely and instructive articles which a man in your business should read in order to be up to date?

¶ Isn't a great part of your time spent in ransacking the various publications in search of these articles? Think of the advantage of having them selected for you each month. How much more profitable your time devoted to reading would be. This is exactly what

THE BUSY MAN'S MAGAZINE

will do for you.

¶ It will select the timely, interesting, and entertaining articles from the CURRENT issues of the world's magazines and periodicals.

¶ Each issue will contain the Cream, the Choicest, and the Best appearing in the magazines of the month.
Write for a sample copy TO-DAY.

The Technical Publishing Co., Limited
287 Deansgate, MANCHESTER, ENGLAND

DO YOU KNOW that there is no other magazine in the world that covers the fields of engineering and technology to the same extent or in such a useful literary way as TECHNICAL LITERATURE, and that no other appeals equally to specialists and the general reader in so many branches of the profession? It has become a most valuable companion to such professional men as

Architects	Engineering Students	Hydraulic Engineers	Mechanics	Patent Attorneys
Chemists	Factory Managers	Iron and Steel Makers	Metallurgists	Power Consumers
Civil Engineers	Foundrymen	Irrigation Engineers	Mining Engineers	Railroad Engineers
Contractors	Gas Engineers	Machine Tool Makers	Municipal Engineers	Sanitary Engineers
Draftsmen	Heating, Lighting and Ventilating Engineers	Marine Engineers	Oil, Paint and Varnish Makers	Steam Engineers
Electrical Engineers		Mechanical Engineers		Water Works Engineers

AND OTHERS INTERESTED IN TECHNICAL WORK OR STUDY

Such men may be considered as forming the backbone of the citizenship of the country. They are the men who do things, and who control the expenditure of millions of dollars, involving the purchase of all kinds of material and machinery. If you have anything to offer them for business or pleasure, advertise it in TECHNICAL LITERATURE. *Let us show you the scope, vitality and the power of our circulation.*

ONE ADVERTISER WRITES: "Your magazine is a good one and sure of success. It is going to be looked over by a good class of readers, and our advertisement will not be lost in a mass of ill-digested matter."

ADVERTISING RATES SENT ON APPLICATION

Subscription price, $2.00 a year to United States or Mexico; $2.25 to Canada; foreign countries, $2.50. Single copies, 20 cents.

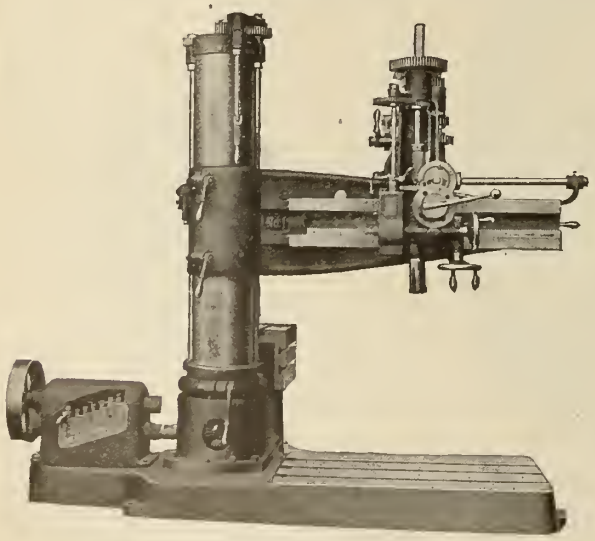
DURABILITY



Improved Plain Radial.

No matter how many cost saving features a machine may possess it will prove a poor investment if frequent repairs are required.

The New Bickford Radial

is designed to run continuously. The bearings are large, speed of all shafts is low and all parts are commensurate with the work required of them.

This is another of those valuable cost reducing features.

Our Radial catalog tells the rest.

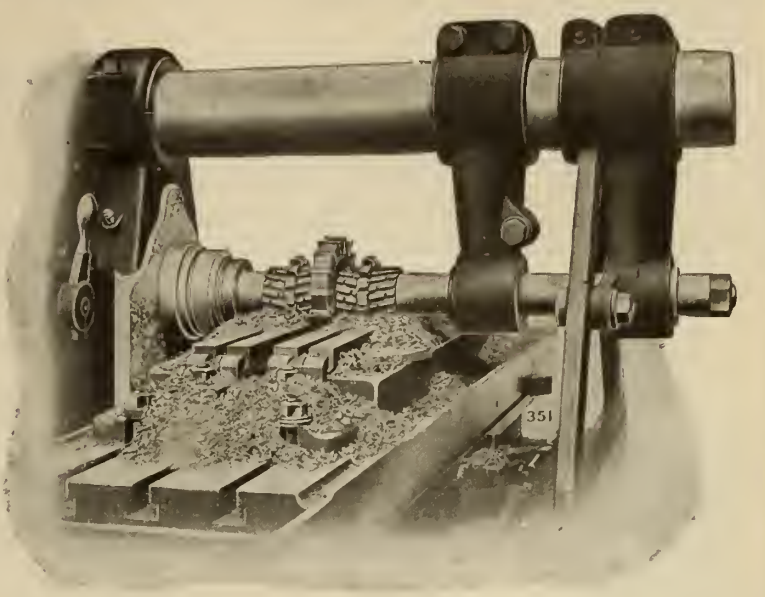
Milling, 9 Minutes
Planing, 36 Minutes

The No. 4 Plain "Cincinnati" Motor Driven Miller

Finishes two of these grey iron castings in 18 minutes, 9 minutes each, including chucking. The actual milling time is 4 minutes on each piece. The pieces are 3 inches wide by 1⅝ inches thick by 25¼ inches long, finished on top and one edge and with a slot ⅝ inch by ⅝ inch cut from the solid. The cutters are High Speed Steel, 8¼ inches, 4¼ inches, and 3 inches diameter, running 38 r. p. m., feeding .100 inch—table travel 3.8 inches per minute.

A 36 inch by 36 inch planer using two heads, working at 55 feet, has not been able to do this work in less than 36 minutes—just four times the milling time.



Have You a "Cincinnati" Miller? ***WE ARE MILLING SPECIALISTS***

No Caliper or Scale for Gisholt Boring Mills

HAVE you ever considered the time it takes to use caliper and scale—considered how much more quickly the work could be done if you did not have to stop the machine for measurements but could bring the cutting tool exactly to the required point while the machine is in motion? Gisholt Boring Mills are equipped with

Micrometer Index Dials

graduated to .001" on both vertical and horizontal feed screws, thus enabling the operator to set the tool quickly and accurately without the use of scale or caliper and without stopping the machine.

Feed Tripping Mechanism

Note the large dials in the small illustration. Through the mechanism controlled by these dials any feed in either direction may be positively and automatically tripped at any predetermined point. No necessity for standing over the machine so as to be sure and trip the feeds at the right place. When the end of the traverse is reached the feed will also trip positively whether dials have been previously set or not. Seven sizes, 30", 36", 42", 52", 60", 64" and 72", all equipped with these devices

CARBORUNDUM
GRINDING WHEELS
MADE AT NIAGARA
USED THE WORLD OVER

There are something like two hundred thousand different sizes and shapes and grades of Carborundum Grinding Wheels—

There are little bits of wheels for the use of jewelers and dentists and there are wheels 3 feet high for grinding car wheels and other big work of that sort—

There are wheels for working marble and granite that do more work and better work than steel tools ever did, and that have practically replaced steel tools in many establishments—

And then there are wheels to do every other sort of grinding work that anybody ever thought of—Carborundum

Does the work faster and better—
Accomplishes more work in a day—
And lasts more days before wearing out than any other abrasive material on earth.

We are constantly making special wheels for special purposes—

We have experts here whose sole duty it is to solve grinding problems —

If you will write us about your grinding requirements we will be glad to tell you just what Carborundum can do for you.

ALUNDUM

A THREE CORNERED ARGUMENT FOR

NORTON GRINDING WHEELS

ADAPTED FOR ALL GRINDING PURPOSES

ALUNDUM is hard, cheap, uniform and of right temper. NORTON GRINDING WHEELS are made of ALUNDUM, and must naturally be more uniform and even throughout than those made of natural or artificial abrasives which vary in purity and uniformity. You can do more and better grinding with ALUNDUM wheels than any others, and we supply all sizes, shapes and grits that modern practice calls for.

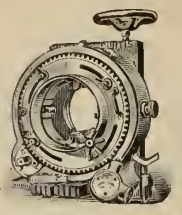
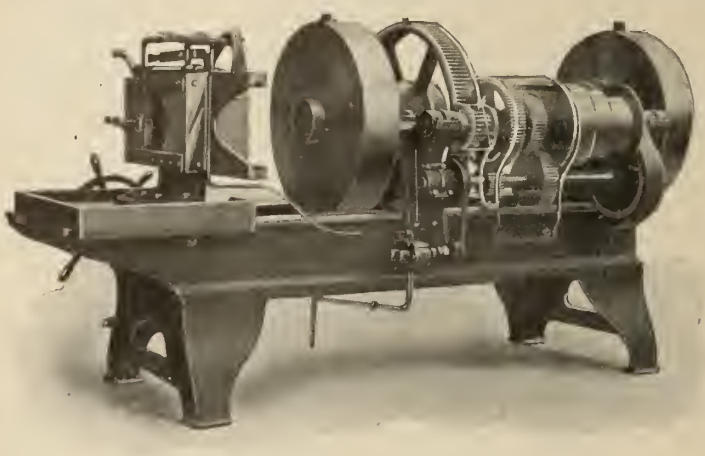
THE CURTIS & CURTIS CO., - *36 Garden Street, Bridgeport, Conn.*





THIS IS THE NEW SHANTZ No. 6.

BAD THREADS—LOST MONEY

That, in brief, is the tale which could be told by many a man who still sticks to his old-fashioned pipe-threading machine. It is surely the worst form of **extravagance** to keep an **obsolete, money-wasting** machine in the shop, especially when, at a reasonable price, the

SHANTZ No. 6

fitted with the **Borden Patent Solid Adjustable Die Head,** may be installed. This machine **cuts absolutely perfect threads** on 1½-inch to 6-inch pipe. It does the work **with one cut,** and does it quicker and cleaner than any other machine in America. **Absolute accuracy** can be obtained by the mere adjustment of an adjusting screw. This machine weighs 4,300 pounds, and is **so immovably rigid** that **a wavy thread is an impossibility.** And there are other points about it, which, with those above stated, place the **"Shantz No. 6"** in a class by itself. **Write for our free descriptive circular.**

I. E. SHANTZ & CO., Berlin, Ont.

The Canadian Fairbanks Co., Ltd.

MONTREAL TORONTO WINNIPEG VANCOUVER

Modern Canadian Manufacturing Plants.

ARTICLE XXIII.—John Bertram & Sons Co., Limited, Dundas, Ont.

The demand for machine tools in Canada has very greatly increased in the last few years and Canadian manufacturers of this line are doing their utmost to keep up with the great expansion of business. To be better able to cater to the trade John Bertram & Sons Co. entered into an agreement with the Niles-Bement-Pond Company in 1905 whereby the experience of the oldest and largest machine tool builders in the United States was obtained for Canadian users of this machinery. This arrangement gave the John Bertram & Sons Company a largely increased trade and additional floor space for handling it was necessitated. Under the direction of L. A. Somerville, supervising engineer, of Hamilton, new and large additions have just been completed which enable the company to better meet the requirements of the trade. It shows the confidence that the industrial men of Canada are placing in its future and the result in this case is a modern up-to-date plant.

The plant is favorably located at Dundas, Ont., a short trolley ride from Hamilton and connected to the Toronto, Hamilton and Buffalo by means of fie switches which we show in the general plan in Fig. 1. It is seen from this illustration that tlie company has ample store room and manufacturing space. The site covers altogether about fifteen acres and the plant is one of the most notable engaged in the manufacture of machine tools in Canada and United States in the variety and ranges of sizes of its products.

Fig. 2—Bird's-eye View of the Plant.

History of the Company's Growth.

The business was started in 1861 as McKecknie & Bertram in a small building located on the site of the present office. In 1865 these men assumed the name of the Canada Tool Works and branched out into special lines, erecting a large building 24x40 feet to carry on the work. This name, The Canada Tool Works, has still been retained, though the company is now more popularly known throughout the Dominion as The John Bertram & Sons, Company, Limited. A few years later this building was burned and was immediately replaced by a rough-cast building 60x40 feet. In 1868 a two-storey brick building was added and then extended in the front. Later a molding shop was added in the rear and finally the triangle was closed by the erection of a two-storey brick structure, leaving in the centre an area of 80x100 feet. Messrs. McKecknie & Bertram worked together until 1886 when the partnership was dissolved and from that time on it has been known as John Bertram & Sons. Building operations were continued in 1899, when this company erected a steel structure, converting the hollow area enclosed by the original buildings into an erecting shop, equipped with a 20-ton traveling crane and a railroad track communicating with all the other departments. This structure is one storey with a clear height of 28 feet overhead and is roofed with heavy glass and corrugated iron. The progress of the works is shown in the number of men employed. Six years ago 150 were given employment and there are now 425 enrolled.

The directors of the company are Henry and Alex. Bertram, sons of the founder, John Bertram, who died April 4, 1906.

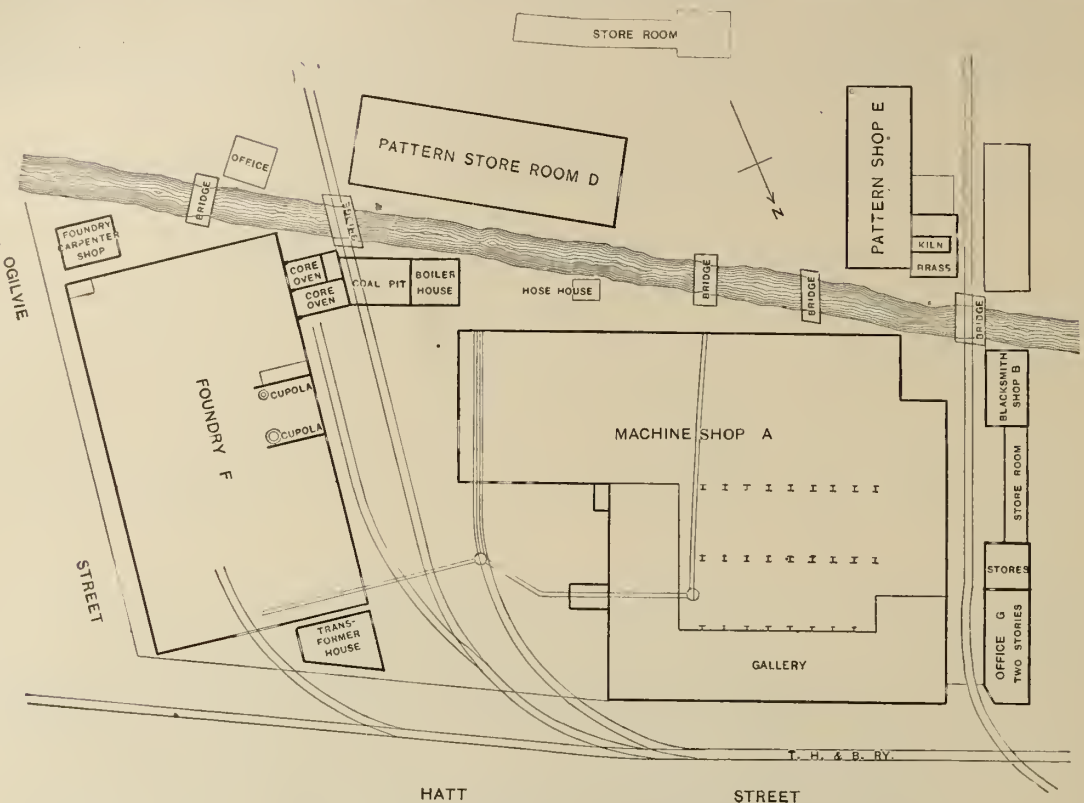

Fig. 1—General Layout of John Bertram & Sons Co., Limited.

The Machine and Erecting Shop.

To the person uninitiated in the manufacture of large machinery it would seem that the manufacture of these immense planers, boring mills, turning lathes, etc., is a large problem, and so it is, but a look into the Bertram machine shop shows that every facility available is used for the handling and machining of the work. One striking feature of this department is that nearly all the manufacturing machinery is the output of their own shop. In Fig. 1 is shown a general plan with the relations of the buildings to each other and in Fig. 2 we show a bird's eye view of the plant, giving the reader an idea of the extensive works. Fig. 3 is a plan of the machine shop and its gallery, showing the arrangement of the tools. The tools are grouped following a scheme of keeping close together those employed in the construction of each type of product. Erecting shop No. 1 is devoted to the erection of boring mills up to 48 inches and planers; large boring mills, drill presses, wheel lathes, etc., are erected in No. 2 and large and special machines

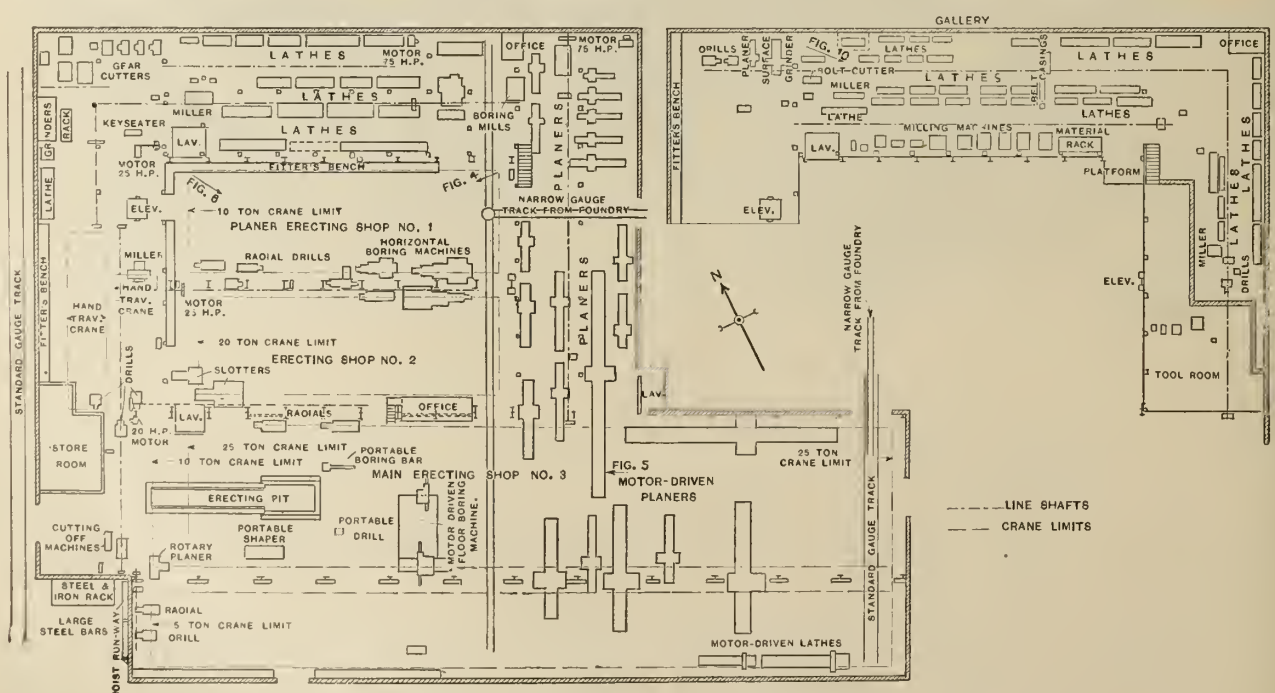

Fig. 3—Plan of Machine and Erecting Shops and Gallery Showing Location of Tools.

in the main erecting shop No. 3. This main erecting shop has just been completed and extends about 84 feet beyond the older buildings and is much higher, making it particularly convenient for the erection of large machines. The new buildings are brick and steel on concrete foundations.

The shops are roomy and well lighted. The present floor space is 67,000 square feet, including 12,000 square feet in the gallery. Illustrations 4, 5, 6 and 7 give a good conception of the machine department. Fig. 7 is taken from the position marked Fig. 10 in our plan No. 3. Fig. 4 shows best the erecting shops Nos. 1 and 2. No. 3 may be partly seen in the left background. A better view of the shop is given in Fig. 5, which shows a large 10-foot planer in progress of construction. All standard planers are erected in the section of the shop shown in Fig. 6. In general, the large work is done on the ground floor and the machining of the small parts is carried on as far as possible in the gallery, a view of which is given in Fig. 7. By a study of Fig. 3 one may get a good idea of the layout of the shop. The arrows indicate the direction the camera was placed on taking the photographs. On the left of the west entrance is a store-room for special sizes of steel and cap screws. To the left in Fig. 5 may be seen the office of the shop engineer and the assistant-superintendent. From this lookout these officers have a complete view of the machine and erecting departments.

As far as possible the machinery is arranged along the walls of the building, leaving the central space free for assembling purposes. The machinery requiring crane services is arranged as close to the centre but does not encroach on the erecting space. The planers are arranged as shown in Fig. 3. Small shapers and fast planers are placed together and the planers get larger towards the south part of the building. One planer is a 60-inch, is 60 feet long and planes 36-foot stock. Larger planers, 96-inch and 106-inch, are also in service. With all the tools the shop is not overcrowded, although it contains over 170 separate pieces of equipment exclusive of benches. In all, there are probably about 60 lathes, including engine, hand, turret, gap, boring, chuck and pulley lathes; 22 planers and a rotary planer, 7-gear cutting machines, 12 milling machines and a complete equipment of radial and upright drills, grind-stones and tool and drill grinders shapers, horizontal boring machines and vertical boring mills, universal and surface grinders, slotters, key seating machines, bolt cutters, power hack saws, cutting-off machines, etc. Some of the machines are very large and include a lathe with 28-foot bed

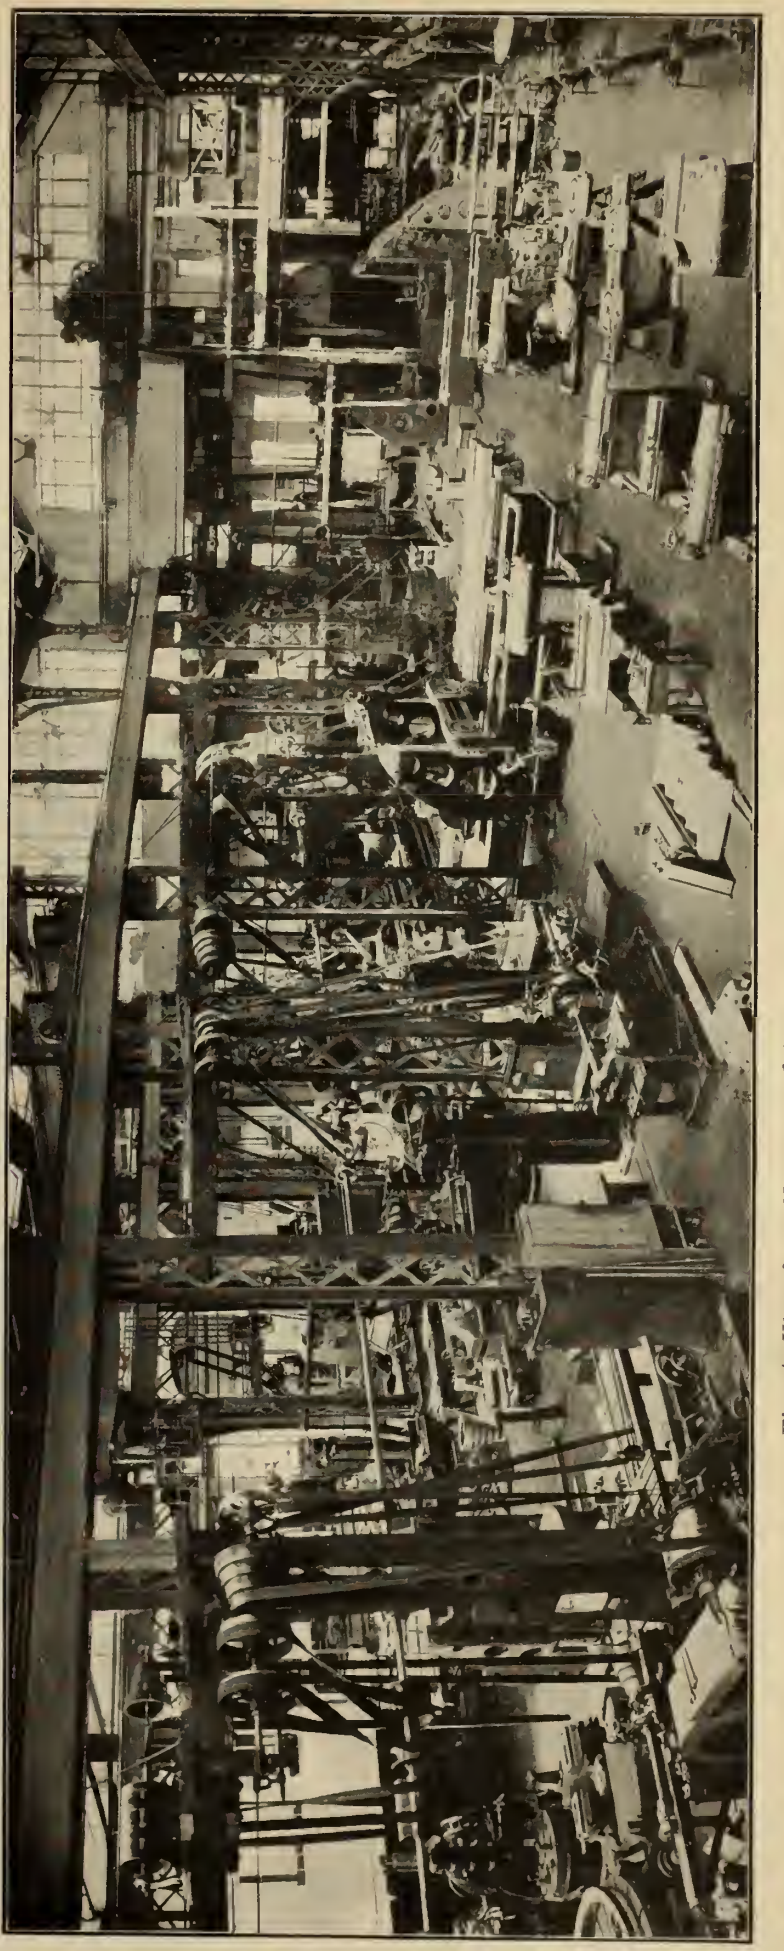

Fig. 4—View from Northeast Gallery, Showing Erecting Shops Nos. 1, 2 and 3.

swinging 72-inches, short lathes of 12 feet swinging 36 inches, and 26 feet swing 28 inches. The largest planer is a 72 x 94½ inch x 36 foot machine. One larger than this for their own use is now in course of erection. An other large planer 36 feet long, is 60 x 48 inches between the housings and there are several 36 x 36 and one 72 x 72 x 20 feet. All the machinery except that in the gallery is on concrete foundations.

Some of the machinery is very interesting. The machinery for cutting the mitre gears are unique and are automatic

the boring tool is kept cool and the chips carried out. A spiral gear machine is next with an equipment of rope pulleys so arranged that either spiral or straight gears may be cut. One man attends these two lathes. Polishing is all done on machines for the purpose, so that there is a uniformity in all small parts. All the gears from 18 to 24 inches are finished upstairs while up to 60 inches are finished on the ground floor. All the machinery for the cutting of gears is automatic-dividing and one man takes care of several machines. Small parts, such as lathe sadders, heads

required were sufficient to warrant it direct connected motors are employed.

Handling the Work.

The floor of the foundry is one foot above the level of the machine shop and a narrow gauge track equipped with turntables permits the work to be moved from the foundry to any part of the machine department. In Fig. 1 we show the narrow gauge track and the two ways in which castings are brought into the machine shop. The heavy castings are taken to the main erecting shop and the smaller to Nos. 1 and 2, where they are

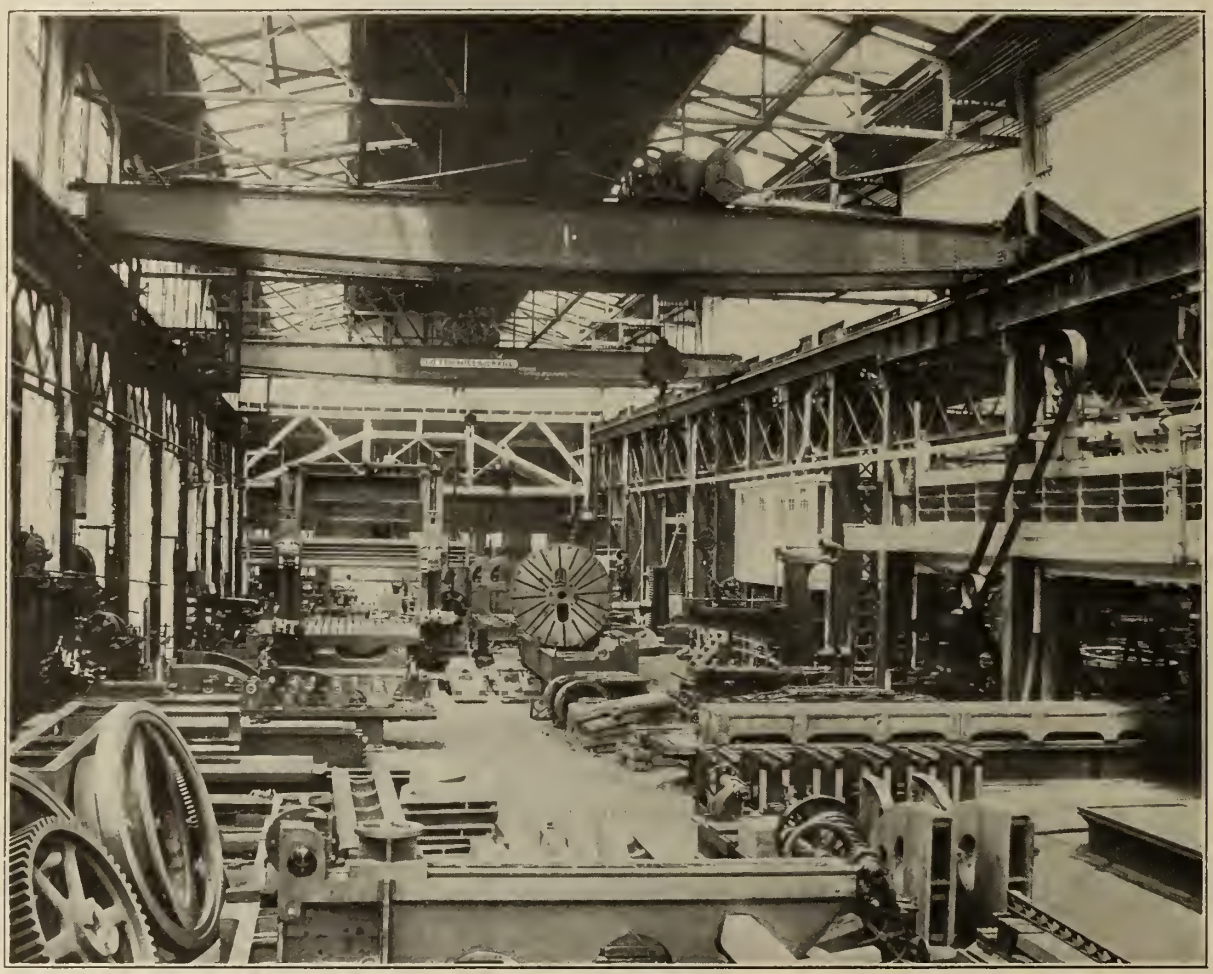

Fig. 5—View from East End of Main Erecting Shop.

shapers. These are situated in the north-west corner of the building. A series of cams the bevel of the teeth to be cut and curves corresponding to these teeth give shape to the teeth. The tool travels absolutely towards the centre giving a correctly shaped tooth that cannot be obtained by rotary cutters. All the gears are divided automatically and the large gears are finished on the ground floor.

In the gallery each turret is equipped with special features for special classes of work. Here the lathe spindles are bored and by an arrangement of a stuffing box, oil pump and open centre drill,

and aprons are assembled on the west end of the gallery.

Throughout the shops are several interesting portable tools, including a portable boring bar, a special portable shaper and a portable electric drill. The machines are group and individual driven suitable for the purposes for which they are intended. In the plan of the machine shop the lines of shafting are indicated and the location of the driving motors with their sizes are given. All the tools in the main erecting shop are driven by individual motors and in other cases where the location or the power

distributed among the machines according to the operations to be performed on them. The castings are passed along the shop from one end to the other on the different machines and pass out at the west side a completed article, so that the work is one of progression, little handling being necessary. Electric cranes facilitate the handling of the heavy machinery. In erecting shop No. 1 thre is a 10-ton crane, in No. 2 a 15-ton crane, in the main assembling room, No. 3, one 25-ton crane, with a 5-ton auxiliary hoist and one 10-ton crane, and in the bay adjoining the latter shop, a 5-ton crane. West of erecting shop, No.

2, are two hand cranes for use there. A system of compressed air is used for hoists and chipping hammers. Babbit for bearings is melted by an electric furnace situated in the bay adjoining erecting shop No. 2.

Tool Room.

This department is situated in the east side of the gallery as indicated in Fig. 3. A check system is used in connection with this department and when a man requires a tool or gauge he hands in a check with his number and becomes responsible for the tool. The tool room is responsible for the standard sizes of

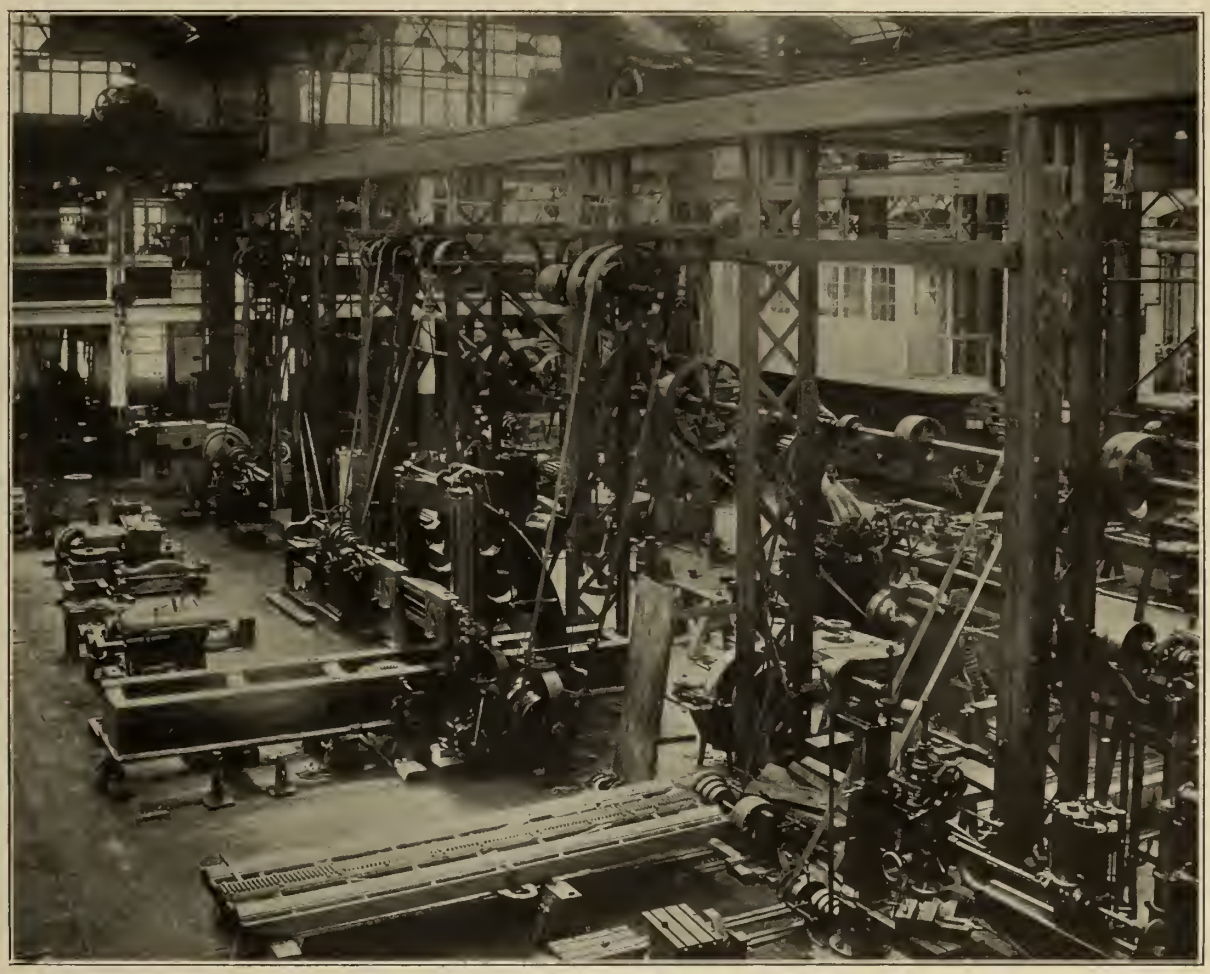

Fig. 6—View in Planer Section from Northwest Corner of the Gallery.

all tools. All shafts and bearings are turned to fixed gauges and then ground and lapped. All the reamers, taps, dies, drills, milling cutters are kept to standard and jigs are made in the tool room. Standard lead screws for the lathes are kept and if the lathes are found to vary from this then the lead screw is replaced. All the machinery, in like manner, is accurate and before a machine leaves the works it is thoroughly tested. Drawings of each part are made with every piece numbered and dimensions given. An elaborate cost system has been established. Men charge their time against the several jobs each night. Small pieces which are done in quantity, are charged to stock and when used for a machine are charged against it. As soon as the work is finished the cost keeper can tell absolutely the cost of the machine or the detailed cost.

The location of the plant has a great advantage, as it comes within the zone of electric current distribution from the various Niagara water-power developments. The power used by Bertrams' is generated at De Cew Falls, near St. Catharines and is purchased from the Dominion Power and Traction Company, of Hamilton. Alternating current is transmitted at 60,000 volts to Hamilton, and from there to a point near Dundas at 10,000 volts, where it is transformed to 2,400 volts at which voltage it is received at the plant and finally stepped down to 220 volts. Alternating current at this pressure is used directly for lighting and the constant speed motors and is converted to 220-volt direct current for variable speed motors on individually driven tools and on all cranes. All of the substation apparatus is contained in the transformer house an entirely fireproof structure and includes four 250-KW static transformers which reduce the pressure to 220 volts, a 175-KW, motor-generator, which takes 220-volt alternating current and delivers 220 volts direct current, a 175-H.P. induction motor driving a Canadian Rand air compressor supplying air at 100 pounds pressure for use in various parts of the plant, and a 1,000-gal. triplex fire pump, which, when occasion requires, may be instantly connected by a clutch to the same motor, the air compressor being disconnected. The pump supplies, three 6-inch mains extending about the works for high pressure fire protection. The motor-generator set was furnished by the Canadian General Electric Co., and the motor and transformer by the Canadian Westinghouse Co. A large 4-panel switch-board with General Electric equipment, controls the distribution to different parts of the plant. The boiler house is 25 by 30 feet and furnishes heat to all the building, two large boilers being run during the winter. Pumps return the condensation to the boilers. A convenient arrangement for reducing the handling of coal has been effected by placing the firing floor of the boilers below the charging floor. Coal is received in cars on a spur track between the foundry and machine shop and dumped directly into a pit beside the boiler-house. The latter holds a considerable supply and delivers

it through grates directly upon the firing floor, by gravity.

The photographs will give the reader an idea of the natural lighting. Both natural and electric lighting are exceptional. All buildings are well-lighted in the daytime. The artificial illumination for dark days, early dusk or night work when necessary is such as to render working practically as easy as by bright sunlight and is afforded by Nernst lamps, no separate incandescent lights are used at the individual machines. This is the first installation of Nernst lamps on a large scale in Canada and the experience with them has been very satisfactory. The lights are so arranged that light is distributed uniformly.

The Foundry.

The equipment is modern in every respect, and everything is arranged to be most favorable to economy of time and labor. The cupolas are arranged along the west side and are a Collion 66 inches in diameter of 14 tons per hour capacity and a Whitney Foundry & Equipment Company's cupola 40 inches inside diameter of 7 tons per hour capacity. There is a full equipment of core ovens, a No. 6 Root blower driven by a 40 h.p. Westinghouse induction motor, Hamilton Facing Mill Company's sand sifters and powder mixers,and an elevating and conveying system supplied by the Waterous Engine Works Co., Brantford, Ont.

One of the most interesting features is the means provided for holding down large floor moulds. This consists of a system of grillage embedded 7½ feet below the floor surface, and binding hooks are inserted to hold down copes of large moulds made in the floor. Air rammers are provided, cranes and natural gas to harden the skin of the moulds, which is necessary in large moulds. In our May issue, 1906, we gave a detailed description of the foundry with its equipment.

Pattern Shop and Vault.

The pattern shop consists of the usual equipment of a drying kiln and a full line of saws, planers and surfacers, lathes, bandsaws and jointers. The stock patterns are well made from seasoned lumber, and when not in use are stored in the pattern vault. Here the patterns with core boxes are piled away in bins and shelves, according to number. A look through this building gives one an idea of the amount of money invested and the years of labor to place on the market Bertram's list of machines and tools.

Other Buildings.

Attached to the pattern shop is a brass foundry. The blacksmith shop is 25x45 feet equipped with forges, annealing and tempering furnaces, and an 800-pound steam hammer. The office is a two-storey building, accommodating the business offices on the ground floor and drafting, blue printing, and photographic departments on the second floor.

This is the important work in connection with any establishment. The output of the John Bertram & Sons Company is varied, but the workmanship is of the best and the greatest care is exercised in the machining of all parts. The company make a specialty of railroad machinery and have recently shipped an immense driving wheel lathe with individual drive to the Canadian Locomotive Company, Kingston; a 100-inch swing lathe of the same type weighing 115,000 pounds to the Intercolonial Works, Moncton; two coach wheel lathes, 42-inch swing for the C.P.R. at Winnipeg and one of the same type for their Angus shops. In course of construction are four large multiple punches and

Fig. 7—View of Machine Shop Gallery.

shears for the Dominion Bridge Co., Montreal. These are 8 and 12 punches up to 15-16-inch diameter with individual electric drive and the shears are for angles 8x8 inches by 1 inch, cutting from 60 to 90 degree angles. Another large machine in course of erection is a large planer 10x10 feet and 20 feet long. It has four cutting tools and these are raised and lowered by four Canadian Westinghouse motors. The planer is individually driven and is for the Canadian Westinghouse Company.

Although making a specialty of bridge builders' and locomotive machinery, the company include in its list of standard tools manufactured, shaping, slotting, boring and drilling machines, vertical boring and turning mills, cutting-off machines, bolt cutting and nut-tapping machinery, punching and shearing machines, plate planing machines, plate bending rolls, steam hammers and horizontal bending and forming machines. Though the range of product is so extensive the excellence of the individual tool has been kept up and a name for quality has been established on the market.

EVANS ROTARY ENGINE.

Considerable experimenting has been done in the line of rotary engines, and Mr. Evans has now placed on the market an engine for commercial use, built along that line. A complete equipment of this type, with a 20-horse power engine, takes up very little space. The boiler is 22 inch x 22 inch x 19 inch. The engine is 18 inch x 18 inch, and underneath the engine shaft is an Evans rotary pump occupying a space 6 inch x 6 inch. Engine and pump weigh only 550 pounds. One sight-feed lubricator

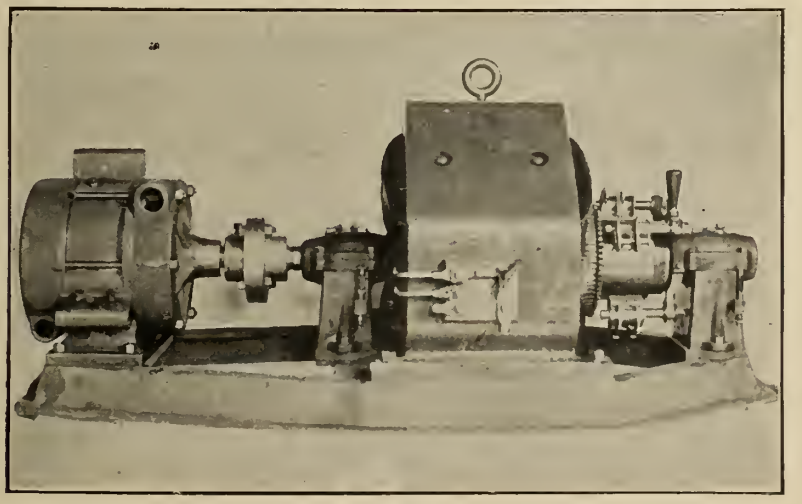

Fig. 1—25-h.p. Directly Connected to Electric Generator.

supplies the engine with oil, and a full way valves controls the direction of rotation.

The cylinder is in three compartments, of 120 degrees, and there are three admissions in one revolution. The cylinder heads fit into the cylinder, and are slotted to support the dividing walls. These dividing walls shown in

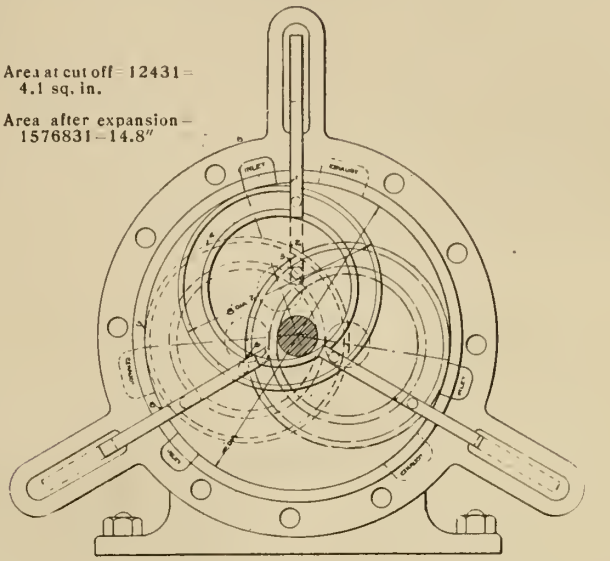

Fig. 2—Positions of Cylinder at the Points of Cut-off and Exhaust.

Fig. 2 keep steam in one chamber from mingling with the steam in another. The steam valve fits on to the shaft by means of a taper key so that it can be placed in one position only, thus the valve makes the same number of revolutions per minute as the shaft and piston. The steam valve consists of two parts. The disc and a sliding annular plate containing the same number of openings as the disc upon which it is carried. Similar valves set in opposite directions are at either end. The three compartments each have a separate steam entry and exhaust port. These ports are similar, each being on alternate sides. The dividing walls are supported on both sides for the whole length by the grooves in the cylinder heads, and also by the whole width of the pockets, the cylinder walls having a motion up and down. A rocking shoe is provided at the inner end of each slide. To these shoes, which work in annular grooves in the piston, the walls are attached. The shaft and cylinder are concentric.

The piston is in three parts, two annular rings one-eighth thick interlock with serrated edges over an inner core, bored to receive the crank pin. They are turned down over the sides of the piston so as to carry the grooves for the shoes of the slides and are fastened to the piston by flat annular rings of copper, the outer circumference of the rings being anchored to the inside of the moveable shells and the inner circumference clamped to the piston by clamping rings and screws. The motion of the piston is hypocycloidal.

The action of the engine is interesting and is fully shown in Fig. 2. Steam is taken in for about 100 degrees, and then cut-off occurs. When this position is reached in one, admission begins in chamber next it, and exhaust in the other one in reverse cyclic order. From this it is seen that the M. E. P. is always constant for a given steam pressure. For this reason no fly-wheel is required and the whole equipment occupies very little space. Fig. 1 shows a 25 horse power Evans rotary engine direct connected to an electric generator.

An adjustable cut-off is a feature of the engine. Weights are tested for different speeds, and these weights regulate the speed by giving an early cut-off, this governor acting centrifugally inside the cylinder head.

This engine is being placed on the market by the Evans Rotary Engine Company, Manning Arcade, King street west, Toronto, Ontario.

CANADIAN MACHINERY
and Manufacturing News

A monthly newspaper devoted to machinery and manufacturing interests, mechanical and electrical trades, the foundry, technical progress, construction and improvement, and to all users of power developed from steam, gas, electricity, compressed air and water in Canada.

PUBLICITY.

The total membership of the Canadian Manufacturers' Association is now 2,189. Only eight years ago this organization had a membership of 132. There must be some good reason for the rapid growth, not only of this Association, but of all the engineering societies and industrial organizations, as well. Making a study of the progress of the different manufacturing countries, the reason appears to be that with the increased membership of these organizations has come increased progress, more business and a great advance in machine shop and engineering practice hitherto unthought of. The conference of the Electrical Association in Montreal has suggested ideas to hundreds of brains, the C.M.A. convention in Toronto has stimulated manufacturers to do greater things in the future, and with a united interest to work for the welfare and progress of Canada and Canadian industries. But we believe there is another potent factor working for the improvement of our machinery and an increase in trade. We believe that the trade journals have done much to develop industries. With the aid of employers and engineers they are distributing with a free hand the experiments, results, data and tests that are being made. To this is due much of the development and growth. Take a country where there is no publicity, where trade secrets are carefully guarded and you see a country where little progress is being made. At the C.M.A., Mr. Emery, of New York, pointed out that Germany, in the last quarter of a century, had made wonderful progress. This is partly because of her industrial educational system, but it is in no small measure due to the publicity given in the last few years to working methods. It may assist one particular manufacturer to keep a trade secret for a time, but it will retard development and trade, and if a nation is to forge ahead it must be by mechanical men, superintendents, foremen and employes gathering together in the different organizations and exchanging their ideas. Manufacturers have realized this and are no longer keeping the information to themselves, but by giving and receiving are helping others and benefiting themselves. Trade papers are the greatest aid in this connection. They reach men who cannot attend these conventions and good ideas that would otherwise be lost are brought to the notice of the other manufacturers, superintendents, foremen and employes. Canadian Machinery devotes a large amount of space each month to machine shop practice, and we believe we are assisting in the work of improving the design and construction of machinery, making workmen more efficient by the new methods and devices which appear each month and stimulating that spirit of industry and progress that should be instilled into every manufacturer, every superintendent or foreman, every engineer and employe, if we are to make Canada a great industrial nation. If any reader has a good idea we trust he will assist by passing it along.

PUBLIC PRESS VERSUS TECHNICAL JOURNALS.

At the regular meeting of the Engineers' Club, of Toronto, on Thursday evening, October 10th, the question arose whether public press or technical journals should be resorted to for the discussion of engineering problems. As a great majority of people do not read the technical journals, questions of general interest and those involving public monies should be discussed in the public press. The public press, however, is not a place for engineering controversy. Engineers should look to the technical press for information, and if the technical press is to be most efficient and be of greatest service to the engineering profession, engineers should use its columns for the dissemination of information. The technical press is for the engineering profession, and to be of greatest value, the engineer and the mechanic and the superintendent must take an interest in it. If he has had a interesting experience, if he has accomplished an unusual piece of work, then a description of the work in the technical journals will be of great assistance to the engineering profession. The engineers outside the cities have not the same facilities for the exchange of ideas, they have not the privileges of a society, and they must depend on the technical journals if they are to keep in touch with the rapid strides being made in the engineering world. One of the objects of a society is to facilitate the acquire-

ment and interchange of professional knowledge, and to promote and stimulate investigation into the several branches connected with the profession. In this the object of the society and technical press is mutual, and the columns of Canadian Machinery are open to the mechanic or engineer who has anything of interest to pass along to his brothers in the profession.

QUEBEC BRIDGE.

The Government Commission is making a thorough investigation into the cause of the disaster and have examined Mr. E. A. Hoare, the Quebec Bridge Company's engineer, and Mr. Collingwood Schrieber, consulting engineer of the railway department, that department having approved of the plans. The following statement has been made by the Commission as a result of their investigation so far:

"As far as we have been able to find out, there has been the greatest care taken all along the line to insure the safety and permanency of the structure. The specifications and plans were prepared by the best engineers on the continent, and wonderful care and accuracy have been shown throughout. We have found absolutely no trace of dishonesty or graft in connection with the construction of the bridge. It seems to be really a case of the best engineering brains on the continent, and the best engineering methods being on trial. In so far as the Government's connection with the enterprise is concerned, every thing seems to be quite regular, and what should have been done has been done."

They have since examined Mr. Cooper, the consulting engineer of the Quebec bridge, in New York, and visited Phoenixville. They will again visit the bridge before submitting their final report on the cause of the disaster. The Montreal Shipping Federation and Board of Trade are agitating that the bridge be rebuilt at a height of two hundred feet, instead of one hundred and fifty feet, which would allow the large steamers with high masts to travel up the St. Lawrence to Montreal.

Mr. Theodore Cooper, before the Commission in New York, declared:

"It was not the best bridge, but the best bridge that could be built with the money. The amount to build it with was limited to a certain extent, and the bridge had to be planned to meet this amount."

Furthermore, Mr. Cooper to a certain extent, emphatically blames both companies; the Quebec Bridge Company, and the Phoenix Company, for the collapse, inasmuch as he is of the opinion that neither had proper officials at the work, men with sufficient technical knowledge to superintend a construction of such magnitude.

"If prompt action had been taken to protect chord 9. west, from further deflection, when the bend was discovered, the Quebec bridge would not have gone down. This would have been only about three hours' work, and the expense would only have been about one hundred dollars in timber and bolts."

If the Commission of enquiry find this to be true, there will be little difficulty in locating the cause of the disaster.

TORONTO UNIVERSITY'S NEW PRESIDENT.

Dr. Robert A. Falconer, of Halifax, was installed as President of Toronto University on September 26, in Convocation Hall, before a large audience of men representing the business, professional, educational and religious men of the country. Dr. Falconer is held in high esteem by those who know him and his opening address showed the firm but sympathetic, inspiring character of the new head of the University. On Wednesday, October 9, he addressed the University of Toronto Engineering Society and referred to the work of the mechanic and the engineer, pointing out that accuracy and a thorough knowledge are essential; in bridge building or any work a man must show a character and this can be done by having an accurate knowledge of details. The selection and installation of such a strong man as Dr. Falconer is of great importance, not only to Ontario as president of the Provincial University, but to the large field where the influence of the university is felt.

TORONTO POWER QUESTION.

The people of Toronto are agitated over the question of Niagara power. At present the Toronto Electric Light Co. is supplying the power for the city, but the Hydro-Electric Commission proposes to supply it at the city limits at $17.75 per horse-power year. Mr. Wright, of the Toronto Electric Light Co., declares that their charge is equivalent to a flat rate of $8.75 per horse-power-per year. The public are anxious for cheap power, and care not whether it comes from a private or a public enterprise. The rate of the Electric Company appears low when operating expenses, depreciation, etc., are all considered. However, the question is worth considering carefully, as it is of great importance to the users of power.

CAUTION AND CONFIDENCE.

The Canadian banking institutions, by their foresight and caution, have averted the possibility of a repetition of New York's experiences in the past week. The retrenchment may have caused a little inconvenience in some quarters, but it has curbed unhealthy speculation and exerted a steadying influence, prudently restraining unsafe expansion in times of prosperity and seeing that retrenchment does not precipitate depression. Canadian trade is still sound, the flurry in the stock market will soon pass over and we will then better appreciate the policy of our financial corporations in their cautious course, which now sustains confidence and courage in Canadian markets.

INDUSTRIAL GROWTH.

The recent census as to the progress of Canadian industries during the period of 1900-1905 gives some valuable information. Capital and output have greatly increased. In the year previous to 1900 the value of manufactured products was 481 million dollars and the merchandise imports 181 million dollars. In 1905 there was an increase of 234 million dollars in manufactures, making 715 million dollars for that year. The imports in 1905 amounted to 256 million dollars. The growth of trade in a period of five years has been enormous and a great many large increases are noted. The manufacture of electrical machines and accessories and other power machines has trebled. The smelting industry has quadrupled and the stone-cutting industry has very greatly increased its output. Canada's industries are growing rapidly each year, and, though they have not displaced the imports to a very great extent, show large returns for the investment.

Canadian Manufacturers' Association

The 36th Annual Conference in King Edward Hotel, Toronto, a Great Success.

The annual convention of the Canadian Manufacturers' was opened Thursday morning, Sept. 24, and was largely attended by the captains of industry who direct Canadian manufacturing enterprises. The session opened with the meeting of the various sections, the larger assemblage afterwards dealing with all matters of general interest. The following officers were elected for the ensuing year:

President—Hon. J. D. Rolland, of the Rolland Paper Co., Montreal.

Vice-President—John Hendry, of the British Columbia Mills, Timber & Trading Co., Vancouver.

Treasurer—George Booth, of the Booth Copper Co., Toronto.

Technical Education Committee—S. Morley Wickett, of Wickett & Craig, tanners, Toronto.

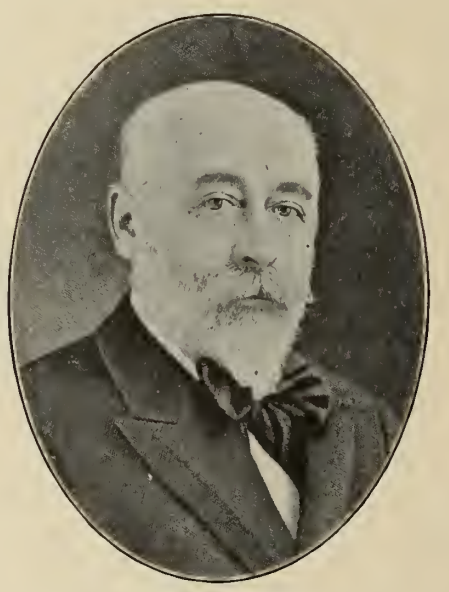
At the meeting of the engine and boiler section, Mr. Leonard, of London, was elected president, and William Inglis, vice-president. At the meeting of this division, Mr. C. H. Waterous occupied the chair, and the chief topic for discussion was an inspection act to govern stationary boilers. The need of a Dominion law was keenly felt, and a long discussion took place on how to obtain such a law and the terms of it. At present a different law exists in each Province, and it makes it difficult for a company in one Province to supply the trade in another Province, and comply with the regulations of the Province in which he is doing business. Steps were taken to overcome this difficulty, and a committee was appointed to confer with experts, find out what was best to do under the circumstances, and report at a special meeting of this section. A special committee will then be elected to confer with the Federal authorities, and, if possible, bring about this new and much needed Dominion Act. At present a Dominion Marine Act governs marine boilers, but this in no way regulates the various other stationary and portable boilers. In our March issue of this year we published an editorial and letters from a number of well-known manufacturers on this topic and all are of the one opinion that a Dominion law is an urgent necessity.

Another matter that the engine and boiler branch took up was the terms of selling engines and boilers, guarantees, check deposits and terms of payment. As it is at present, manufacturers of engines and boilers are quoted F.O.B. cars and others erected. It was desirable that some agreement be arrived at in this matter so that builders of this line of goods would be on equal footing.

Presentation to Ex-President Ballantyne.

An interesting feature was the presentation by Mr. Cockshutt on behalf of the association of an illuminated address to C. C. Ballantyne, of Montreal, ex-president of the association, in recognition of his valuable services.

Another feature of the convention was an address by Archibald Blue, chief officer of the Dominion census, illustrative of the growth of Canada in the twentieth century. Capital and products showed large increases in the five years for every Province of the Dominion, except Prince Edward Island, Ontario and Quebec showing the largest development.



HON. J. D. ROLLAND
President of the Canadian Manufacturers' Association.

The President's Address.

President H. Cockshutt of Brantford, in his annual address, made a strong plea for higher protection, as well as for a more vigorous forestry policy, providing for an export duty on pulpwood, so that this industry would be developed in the country to which the raw material belongs. After touching upon the fishing and mining industries, he pointed out that manufacturing showed progress and activity, the output of the factories in the last five years having increased from $481,053,371 to $717,118,092.

Reception by Toronto Branch in the Evening.

The reception tendered the visiting manufacturers and their wives by the Toronto colleagues at the King Edward was brilliant and pleasant. A delightful programme was given, contributed to by Mrs. Freyseng, and Messrs. Arthur Blight and Howard Massey Frederick, and promenading was enjoyed to sweet strains of the orchestra.

WEDNESDAY, SEPTEMBER 25TH.

Prof. Fernow, Professor of Forestry at Toronto University, spoke to the association in the morning on "Reforestration," and said that a forester's work did not begin when the country was deforested. It should begin when the first tree was cut, and so render the laborious and expensive system of artificial reforesting unnecessary. For the Government to take control of the timber holdings would be a proper method of treatment of our timber resources.

The ladies, who had come with their husbands to the city, spent the afternoon at the Lampton Golf Links. The Tariff Committee gave their report at the afternoon session, and the keynote was adequate protection for Canadian industries.

In the evening the delegates were the guests of the Toronto branch at the Royal Alexandra Theatre.

THURSDAY, SEPTEMBER 26TH.

Industrial Education.

The needs of industrial education in Canada were ably expressed before the Canadian Manufacturers' Association at this morning's session by Mr. James A. Emery, of New York.

Mr. Emery pointed out how much more necessary efficient workmanship is to the manufacturer every day.

"Remember this," he said, "that both labor and capital are dependent for profit on increased production by superior methods. President Roosevelt says, 'The man behind the gun is the man who makes the way,' and the man behind the machine is the man who makes the industry. Gentlemen, there never was more need in the land for industrial efficiency."

Mr. Emery then illustrated how Germany had risen in thirty years from the bottom of the scale to the second place among manufacturing nations by industrial education. "Canada should

not be any more dependent on other nations for men, than for material," he said.

Then followed a paper by Mr. L. G. Read, of Montreal, on "Power as a Fixed Charge," which we reprint in full on another page.

A garden party was given at the Government House in the afternoon, and in the evening the ladies attended a theatre party at Shea's.

ANNUAL BANQUET.

Nothing could have indicated in a more suggestive way the progress and prosperity of the country than the scene in the beautiful King Edward dining-room Thursday evening, where 350 guests had gathered to hear the foremost statesmen in the Canadian public life. Union Jacks were everywhere and national sentiment permeated the entire gathering.

In proposing the royal toast, Hon. J. D. Rolland, of Montreal, the newly-elected president, thanked the association for the honor they had done him, and referred to the national character of the organization.

Lieutenant-Governor Mortimer Clark replied to the toast, and spoke along the lines of Technical Education, a subject of such vital importance to our manufacturers that we give it in full.

Lieut-Governor's Speech.

The Lieut.-Governor, who had a great reception, said he had read with a very great deal of interest the many subjects which the convention had taken up, and he congratulated the members of the association upon the success which had attended the convention. He felt very much pleasure to find that a paper was read to the convention on the subject of technical education. (Cheers.) "You all know," went on his Honor, "what a very great deal of success amongst the German manufacturers has been the result of technical education to the young in that country. You know also that the result has been to give in some branches of manufactures a very great pre-eminence and a consequent loss of trade to other countries. In Great Britain and here, too, we have suffered from lack of technical education." (Cheers).

He hoped that manufacturers would have their sons avail themselves of the scientific education provided in our great universities, such as Toronto and McGill. He hoped that the Manufacturers' Association would throw the weight of their great influence in seeing that proper technical instruction was afforded to our youth. Our agricultural colleges have largely increased the value of the products of the farm. Technical and scientific schools would do the same for manufacturers. His Honor recommended greater interest in this subject, and said that Canada owed a great deal to the manufacturers. "You have very largely changed the whole complexion of this country. A visit to our Toronto Exhibition would abundantly show this. In past years it was but an exhibit of fine cattle, horses and dairy produce, while to-day it is also a wonderful display of fine machinery and manufactures of great excellence. He remarked that in the past we have too long regarded Canada as a purely agricultural country. We have been slow to admit that agriculture alone will not build up a great country." (Cheers.) His Honor quoted the case of Venice, which for hundreds of years, although built only on sand and piles in the midst of the sea, acquired enormous wealth and commanded the Mediterranean by its navies, and, proceeding, said that agriculture was not alone necessary to build up a great nation. Agriculture was not the source of the prosperity of Great Britain; but it was manufacture which was the source of building up the head of our great Empire. However, at the back of manufacture, we are fortunate in having a magnificent agricultural country to provide an ever-increasing market. For years and years the daily papers toward harvest time were filled with accounts of the condition of the crops. They heard of rust and mildew and the smut and they all seemed to feel that the whole country was going down. Now, however, they hardly heard of anything of the kind; and the manufacturers by building up industries, had done much to do away with this. It would be improper for him to refer to the great question of tariff, "But," added the Lieut-Governor, "I have a very great deal of sympathy with you in your desire to give pre-eminence to the manufacturing industries of this country. (Cheers.) How that may be brought about it is not for me to say." His Honor made a suitable reference to the visit of the British journalists; and, concluding, said it was the duty of the people of Canada to place before the people of other nations the advantages which Canada offers, remarking that there was plenty of British money ready to come to Canada, provided the capitalists were assured of the honesty of the schemes submitted to them and the reliability of our legislation.

Mr. George Tate Blackstock, K.C., proposed the toast to "Canada and the British Empire," and spoke of the relation between Canada and the Mother Country, and referred to our progress and our share in the defence of the Empire.

The Premier Warmly Welcomed.

Sir Wilfrid Laurier responded to the toast and was received with a tumultuous applause. He spoke on many topics most prominent before us, militarism, French treaty and the Asiatic problem. In speaking of diplomatic relations, Sir Wilfrid said that our diplomatic relations carried on by the Mother Country had not been as successful as we would wish them, though the diplomacy had been in the hands of capable men. "We have suffered on the Atlantic, we have suffered on the Pacific, we have suffered on the lakes," he remarked. "Well, we have come to a decision, whether in our relations with foreign countries, it would not be better to manage them ourselves rather than entrust them to the ministers in Great Britain. This long-looked-for reform has at last come to be a living reality." (Cheers.)

Sir Wilfrid spoke of the "All-Red" line, and said he had the fullest confidence in the project. In the undertaking it was necessary to have the assistance of Great Britain, and it was not Canada's place to dictate to the Mother Country.

He did not know that there would be an immediate success for the "All Red" line. It was surrounded with difficulties, but they had no terror for him at all. He had had them all his life, he had them in connection with this scheme and would still have them, but they would be overcome, and this project must, and would, succeed. (Great applause.)

Major George W. Stephens, of Montreal, replied to the transportation toast.

An interesting souvenir given to the members of the C.M.A. at the convention was a paper-weight, consisting of a large ball revolving on a pedestal on ball bearings. With it was a card bearing the following. "May your life have as little friction as this bearing, is the wish of the Chapman Double Ball Bearing Company of Canada, Limited, Toronto."

FRIDAY, SEPTEMBER 27TH.

The business finished, a day was reserved for recreation, and the visitors enjoyed an excursion to Hamilton and Niagara Falls. A visit was paid to the shops of the International Harvester Co., and the Canadian Westinghouse Co., after which the entire party enjoyed a visit around the city. After lunch the party proceeded to Niagara Falls, where the members visited the huge power plants now in operation there. As a close to the successful convention, the Niagara Falls Board of Trade tendered the guests a supper at the Clifton House.

Ice Breaking Car Ferry Steamer

The Machinery Equipment of a Modern Steel Ice-Breaker Being Built at the Polson Iron Works, Limited, Toronto.

On the second of April, 1908, the Canadian Pacific Car and Passenger Transfer Company, Limited, of Prescott, Ontario, will have added to their equipment an up-to-date ice-breaking car ferry steamer now in course of construction in the Polson Iron Works, Toronto. The equipment is in itself a complete factory with its power machinery, electric engine and generator, steering gear, fire equipment, capstans, compasses, engineers' firemens' tools and all the useful fittings for the successful operation of a first-class vessel of this type, complete in every respect.

Principal Dimensions.

Length over all, 280 feet; breadth molded, 40 feet; depth molded, centre, 22 feet; and draft full load, 12 feet. The frames are of channels, 7 inches by 3½ inches, 21 pounds. On every floor plate is an angle bar 3½ inches by 3 inches, 9 pounds. The floor plates are the full depth of the centre keelson, 12 pounds. The floor plates under the boilers are 16 pounds. The centre continuous keelson plates are 36 inches wide and of 18 to 16-pound plate. It is secured to the floor by double vertical angles, 3 inches by 3 inches by 7 pounds. At the bottom of the keelson are two continuous angle bars, 5 inches by 3½ inches by 13 pounds riveted to the keelson and flat steel plate. Two continuous angles, 3½ inches by 3½ inches by 8 pounds are riveted to top of keelson and an 18-pound rider plate will rivet to top of these. Four side intercostal keelsons of 16-pound plate are secured to the floors. Stringers of 15-pound plate are riveted to the steel plating between each frame. The deck beams are channels 10 inches by 3½ inches by 28 pounds.

The ice belt is laid so that lower edge is 40 inches below the load water line, and the upper edge is 20 inches above load water-line and is 30-pound plate. All holes are punched ⅛-inch small and reamed to size. The steamer will have ten bulkheads, which will conform with the requirements of the American Bureau of shipping. All will be water-tight with water-tight manholes and doors. On the deck will be arranged four coaling scuttles with covers and iron gratings so arranged that a hopper-car can dump directly into the coal bunkers. There are two coal bunkers, one at each end of the boiler space. Each bunker has two doors at the fire room.

The Electric Lighting Plant.

This consists of one direct connected engine and generator, 110 volts of 15 kilowatts capacity. The engine and generator are secured on a common bedplate, in the engine room. The bedplate rests in a metal pan with edges turned up two inches, to catch the oil and water and the pan is secured to a wooden base to deaden vibration. The electric generator, switchboard and accessories are furnished by the Canadian Westinghouse Company, of Hamilton. The switchboard consists of three panels of slate 1¼ inches thick and on it are independent switches for each current, one Weston voltmeter, one ammeter, one shunt rheostat to regulate voltage from 10 volts below normal to 10 volts above, one two-light ground detector, one voltmeter switch, one ammeter switch, automatic circuit breaker, two 110-volt pilot lamps, one magneto bell, and one 15 to 150-volt portable voltmeter. There are 166 16-candle-power lamps and two

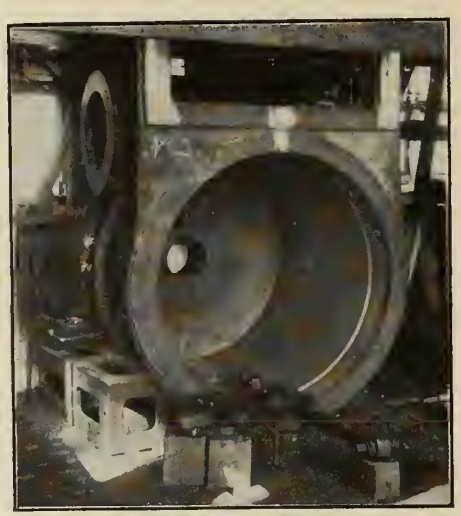


Fig. 1—Low Pressure Cylinder for 1,000 H.P. Engine.

searchlights of 35 amperes capacity. The lamps are designed for the 110-volt system. The wiring throughout the ship is the 2-wire watertight conduit system.

Propelling Engines.

There are two sets of vertical inverted compound jet condensing engines, each driving an independent propeller, one at the forward end and one at the after end. The cylinders are each 24 inches and 48 inches by 30 inches stroke. In Fig. 1 we show one of the low pressure 48-inch cylinders as it was being machined on the planer. This cylinder weighs 8,560 pounds and one pair complete with cylinder covers weigh 20,000 pounds. Each set is capable of developing 1,000 indicated horse-power at about 125 revolutions per minute with a steam pressure of 130 pounds at the boilers. These engines are made especially strong to withstand the severe shocks to which they will be subject. Each engine has an independent jet condenser and air pump, each having two independent suction and discharge. The cylinders are made of hard, close-grained cast-iron. Both cylinders are fitted with relief valves. The cylinder walls are 1¼ inches thick in the barrel, 1⅝ inches thick over the counter-bore at the bottom, and 1½ inches thick over counter-bore at the top. The cylinders of each engine are supported by four cast-iron columns and the bedplate is one casting. Fig. 2 shows the eight columns for the two compound engines. These columns are twelve feet high. The crank shaft bearings in the bedplate are 13 and 15 inches long. The bearing sleeve is of strong bronze lined with the best babbit metal. The cast iron caps are held down by two steel bolts 2¾ inches in diameter with locknuts. The piston is of the box type. All cast-iron is at least 22,000 pounds tensile strength.

Forge Steel Parts.

All forgings are of mild steel 60,000 pounds tensile strength and at least 30 per cent. elongation in 2 inches. The piston rods are 4¾ inches in diameter in the body with 3½ inches diameter of the thread at top and bottom. They are fitted to the cross heads and pistons with cones, collars and steel nuts, case hardened. The cross heads have each two gudgeons 5 inches in diameter by 5½ inches long and the square or block part of the cross head is about 9 inches by 9 inches. The guide slippers are cast-iron and the guide surfaces are babbited.

The connecting rods are 6 feet 3 inches from centre to centre. The body of the rod is tapered from 4 inches at the top to 5½ inches at the bottom. The bearing at the upper end of the rod is brass, the crank pin bearing is of steel lined with babbit metal. The bolts at the crank pin end are 2¾ inches and those at the upper end are 1¾ inches in diameter.

The valves of both cylinders are operated by Stevenson's double link motion. The valve sterns are forge steel, the bearings at the lower end are 3½ inches in diameter by 3 inches long; where the valve stem passes through the guides it is a square section, the sides measuring 2½ inches, where the stem passes through the stuffing box they are 2½ inches in diameter. The links are 4 inches by 1¼ inches with a link travel of 20 inches. The eccentric rods work on pins at the end of the links. The pin for reversing rods was forced in and riveted over. The valve

stem guides are cast iron and each have an adjustable brass lined bearing.

Reversing Gear.

The reversing shaft is wrought steel 4½ inches in diameter. The reversing engine has a cast-iron cylinder 10 inches in diameter by 16 inches stroke. The piston is of cast-iron with spring rings. The cylinder is attached to the low pressure front column and can be seen on the frame in Fig. 2 Control is by means of a flat slide valve actuated by a floating link motion.

The crank webs are cast-steel 7½ inches thick. The crank pins are 10½ inches in diameter by 12 inches long. The thrush shaft is 10½ inches in diameter; has 8 thrust collars 18 inches in diameter, 1⅞ inches thick, forged on. The intermediate shafting is 10 inches and the propeller shaft 11 inches in diameter. The thrust bearing consists of a cast-iron pedestal which is securely bolted to the main engine foundation plate. The thrust is taken up by seven cast-steel horseshoe collars lined with babbit metal and mounted on two Tobin bronze rods 2½ inches in diameter. There is a bearing at each end of the thrust block.

The propellers are cast-steel 9 feet 6 inches in diameter and 10 feet pitch. They are fitted to the shaft with a taper and held in place by a key and nut.

The Boilers.

There are four single-ended return tubular cylindrical boilers built for a working pressure of 130 pounds per square inch. The boilers are operated with Howden's system of forced draft. The air heaters are arranged for this system. The tubes are 2¾ inches in diameter by 4 feet 6 inches long between the tube plates. The ratio of heating surface in heater tubes to grate surface is 18¼ to 1. The tube plates are ¼-inch thick. A Buffalo forge steel plate full housing pulley fan is used with a blast wheel 85 inches in diameter and 42¾ inches wide at centre, inlet 55 inches in diameter and outlet 44½ inches square. The engine for use with this fan is a Buffalo Forge Co. class B of single vertical, double-acting cylinder type direct connected to fan. The cylinder is 7 inches in diameter by 7 inches stroke, crankpin diameter 2¾ inches, length of crankpin 2½ inches, diameter of shaft 3 inches, length of main bearing 6¾ inches, initial steam pressure 125 pounds. This equipment is of sufficient capacity to burn 5,040 pounds of coal per hour and maintain ½-inch air pressure in the ashpits of the boilers.

Duplex single acting air pumps are direct connected to the jet condensers and air pump and condenser are of the Washington type, having cylinders 12 and 28 by 18 inches. Ballast pumps are of the Morris Machine Company's centrifugal direct connected type, with 6-inch suction and 6-inch discharge, the engine is 6 by 6 inches automatic governing type. The arrangement is such that any compartment can be flooded or drained independent of the others. There are two double-acting, duplex brass lined feed pumps of the Worthington type, with cylinders 9 by 5¼ by 10 inches. These pumps are arranged to draw from hotwell or sea and discharge to boilers. The equipment also includes a general service double-acting, duplex brass lined pump of Worthington type with cylinders 7½ by 5 by 6 inches. There are two injectors connected for feeding the boilers. A complete fire equipment insures safety in case of fire.

The engine room is fitted with pipe vise, and bench vise and a complete workman's outfit of hammers, files, wrenches, taps, drills, dies, etc., and the steamer when it reaches Prescott will be complete in every detail. It was designed by M. C. Furstenau, of Philadelphia, but all the working drawings were made at the Polson Works where large contracts are easily and competently handled. The present steamer now under course of construction is for the use of the C.P.R. and New York Central and will ply between Ogdensburg and Prescott, making a closer link between the Canadian and United States lines.

There is a good deal of difference between publicity and advertising—you can shoot a man and get publicity.

NEW PUBLICATIONS.

Journal of Foundry Practice.

With October comes the first issue of a new journal on the art of founding, "Castings," published monthly by the Gardner Printing Company, Cleveland, Ohio, and edited by H. M. Lane and R. I. Clegg. It treats a variety of subjects restricted to one trade, foundry, and is a general foundry publication.

Construction Magazine.

The first issue of Construction has been received from Toronto, a monthly magazine, published by H. Gagnier, Limited, and edited by Ivan S. Macdonald. It wil be devoted to the building and engineering interests.

Fig. 2—Frames for the 1,000 H.P. Engines.

NEW TOOL ROOM LATHE.

Among the machines exhibited at the Toronto National Exhibition by the A. R. Williams Company, Limited, Toronto, was a 16-inch tool room lathe, manufactured by the American Tool Works Company, Cincinnati, Ohio. This lathe created considerable favorable comment and was purchased at the Exhibition by a prominent Canadian manufacturer. It is equipped with relieving and improved taper attachment, and a draw in collect mechanism and pan. Owing to the fact that this lathe arrived after our October issue was in the press, a description of the "American" tool lathe was not included in the machinery exhibit.

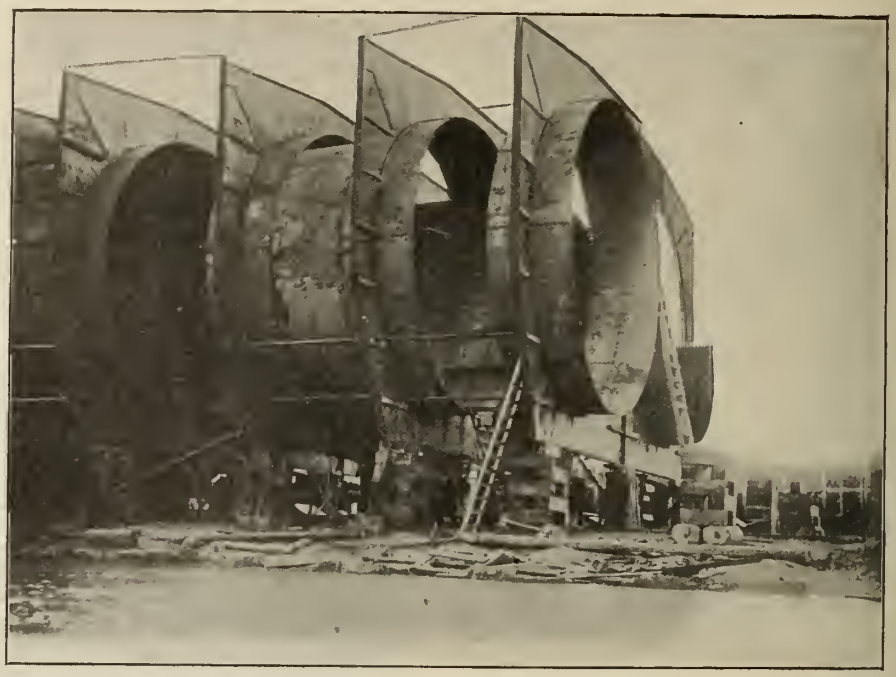
Subaqueous Tunnel

Railroad Tunnel Joining United States and Canada

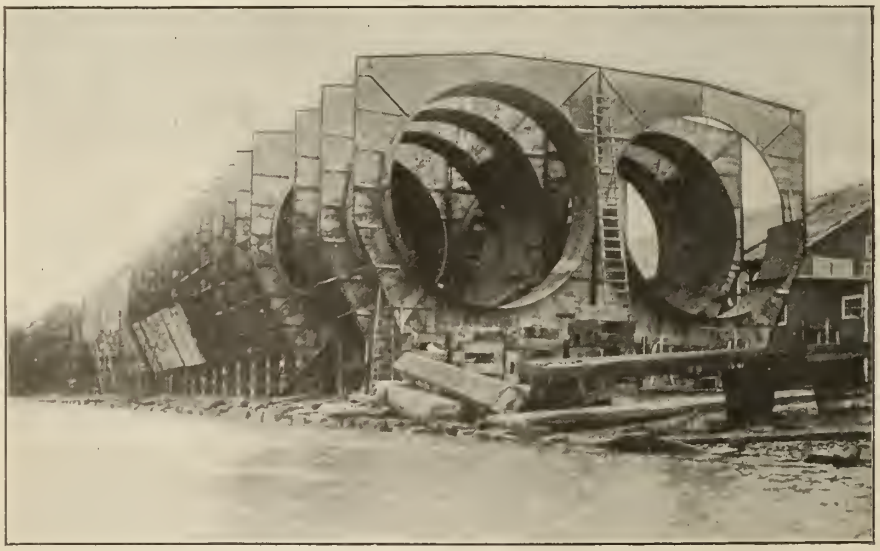
The Michigan Central Railroad, by means of a tunnel, is overcoming the gap in its line where the Detroit River forms the national boundary between United States and Canada. This is the last serious break to be overcome in the whole roadbed of the New York Central lines. The river separating Detroit and Windsor is about three miles wide, and powerful ferry boats make the connection between the two towns.

The bed of the river is soft blue clay and makes the building of a railroad tunnel at this point a very serious undertaking. The vessel traffic up and down the Detroit River is very heavy, and when reckoned in tonnage is about equal to the famous Suez Canal. In considering the project, W. J. Wilgus, vice-president of the New York Central, suggested that a ditch or channel be dredged across the bed of the river, fill it with concrete and then drive the tunnel through it. This would practically be equivalent to making rock and then boring it, and at once an easier method suggested itself to his mind. The form of tunnel decided upon was that of twin tubes, and the method of construction devised by Mr. Wilgus may roughly be described as the "cut and cover" method, as applied to tunnels under water. The method thus evolved consists of dredging a channel or ditch across the bed of the river between the two shores, laying sections of tube in the ditch, connecting them together when in place, filling around and over them with concrete, and then pumping out the water in each of the continuous tubes.

From the illustrations it is seen that the tunnel is composed of twin tubes of steel. The part beneath the water is 2,622 feet in length. The minimum depth over the roof of the tubes is at no place less than 41 feet, which is slightly more than the depth required by navigation laws. On either shore the tubes connect with tunnels by open cuts and through these cars will be drawn by electric locomotives. The work altogether will comprise an electric zone on each side and under the river about 23,000 feet long. A double track enters the cut at the Detroit end, 1,540 feet long, then through a land tunnel 2,129 feet. The subaqueous tube itself comes next, 2,622 feet, and on the Canadian side there is a land tunnel 3,192 feet long and an open cut 3,300 feet in length.



Side View of Tunnel Sections.
(Photo by Detroit News-Tribune.)

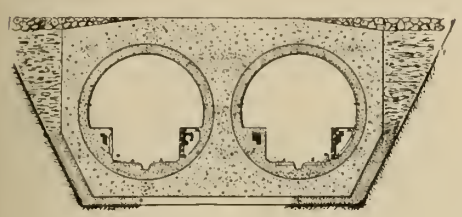


Front View of Tunnel Tubes Connecting Diaphragms.
(Photo by Detroit News-Tribune.)

Our half-tone illustrations show sections of the tubes as they stand in the contractor's yard at St. Clair, Mich. Each section consists of a circular ring of $\frac{3}{8}$-inch steel plate, with a central fin or diaphragm all around it. The tube sections are 250 feet long, and are each 23 feet 4 inches in diameter, and have a concrete lining 20 inches thick which gives a clear diameter of 20 feet. Each tube contains one track and the roof of the tunnel is 18 feet above the rails. Running along the sides of the tunnel are concrete platforms, 5 feet 3 inches above the rail and 3 feet $10\frac{3}{8}$ inches wide on top. In these concrete platforms are contained conduits for signal, lighting and electric power cables, telephone and telegraph. The platforms provide a walk way for passengers in case of necessity, and room for the workmen.

The line cut shows the method of carrying on the work. The dredge, equipped with powerful clam-shell buckets for excavating the trench in the bed of the river, is seen in the distance nearing the Canadian shore. The trench is 48 feet wide at the bottom and about 32 feet deep, with a slope of $\frac{1}{2}$ to 1, so that the ditch is between 50 and 60 feet wide at the top. Behind the

dredges are the pile drivers. Temporary piles are driven into the trench, and the tubes are located on these prior to placing them in the concrete. The piles are driven on either side of the trench in two rows, and are long enough to come up to the surface of the water. These piles guide the tubes so that they



Section of Tunnel, Showing Trench, Filling Concrete, and Tubes.

settle in the required direction. The piles are then removed and used for the further carrying on of the work.

Placing the Tubes.

After the pile drivers come the scows, with derricks, air machinery, hoisting apparatus, drivers' equipments, etc., for placing the tubes. A section of the tunnel, about 250 feet long, containing two tubes and 23 diaphragms, is blocked up at each of the twin tubes with bulkheads of wood and made ready to float on the river. This method makes the tubes air tight. Bolted to the diaphragm is three-inch planking, so that when made ready the section is like a huge wooden vessel with wooden sides, having steel ribs across, holding the tubes. Four temporary floating cylinders, each about 10 feet in diameter, and 60 feet long, are chained on the top of the tubes. These cylinders are filled with compressed air, and with the enclosed air in the main tubes, and the outside planking, the whole section is made buoyant enough to float. The section, thus prepared, is lowered into position between the guide piles in the river and the air allowed to escape from the tubes. Final adjustments are made by the compressed air cylinders. When in position in the trench, the section is joined to the one already down. The tubes shoulder in heavy rubber gaskets at the joints, in each side of which are partially cylindrical chambers. Into these chambers the best grade of cement grout is introduced. The joints are finally locked with heavy pins fitting into corresponding sockets in the adjoining section, and securely bolted. The forward end of each of the tubes has a sleeve 17 inches long, which is fitted over the end of the section already sunk.

Filling in the Concrete.

A concrete mixer, with a set of tremies, distributes the concrete under and around the tubes. These tremies are long steel tubes from 8 to 12 inches in diameter, with a hopper at the upper end. The concrete is filled into the hopper and the concrete is distributed along the tubes evenly by moving the lower end along the bottom. In this manner the cement is deposited in the bed of the river, with very little loss. The scow for this work is about 135 feet long by 35 feet wide, with three tremies on each side. Concrete made of one part cement, three of sand and six of broken stone is poured in between the 3-inch planking and the steel tubes. This concrete fills around the tubes completely and covers them to a depth of about 4 feet 6 inches. The space between the slope sides of the trench and the planking is filled in with sand, gravel and a covering of stone. When the tubes are finally in position, the wooden bulkhead at the end of the section is removed and the water pumped out. The danger of the undertaking has been lessened by a great deal of the work being done at the surface. On account of locating the tunnel on the river bed, the grade is 2 per cent. at the Detroit end, and 1.5 at the Windsor end, much less than if the tunnel had been built below the bed of the river. The tunnel will cost $10,000,000, and it is expected that it will be completed by June, 1909.

DEATH OF MR. W. H. WIGGIN.

In the death of William H. Wiggin, superintendent of the International Harvester Company of Canada, Hamilton, Ontario, the company has lost a man of exceptional executive ability and an able mechanical expert.

Mr. Willin was born in Dracut, Mass., and served his apprenticeship in his native State. He there gained a reputation as an expert mechanic, and his motto, "It Can Be Done," is worthy of being followed by every young man starting out in the battle of life. Mr. Wiggin was ill for several months, and though able professional men from Canada and the United States were called in consultation, he passed away on Oct. 2. His last remains were conveyed to Worcester, Mass., the scene of his early boyhood, where interment took place on Friday, Oct. 4.

INTERNATIONAL JAPANESE EXHIBITION.

Construction work has already been started for the International Japanese exhibition, which is to be held in Tokio next year. The total cost of the exhibition has been estimated at $10,000,000; one-half of this amount has been set aside by the Government of Japan, while private citizens have subscribed the remainder. The exhibition is to open April 1st, and will last until October 15th. Some of the principal exhibits will be of a scientific character.

Power as a Fixed Charge*

The Load Factor is Pointed out to be of Utmost Importance in Measuring Power Used and in Calculating True Costs

By L. G. READ

To give full consideration to the great question of power—the backbone of all industry, the one most vital requisite to material progress—would require time far beyond that which is at my disposal on this occasion. Nor can we view the broader and more interesting subject to the evolution of power—the advent of steam—with its quickening of the world's pulse and its development of its tremendous resources within almost a single generation. We are, therefore, compelled to deal briefly—to deliver, as it were, a little address on a big subject.

We must deal directly with the facts as we see them today. On the one hand are the manufacturers, with their almost countless thousands of employes, engaged in the most highly legitimate pursuit conceivable—the conversion of raw material into finished product for the infinite needs of mankind. On the other, the coal supply. Or let it be called by its proper name, the Coal Trust, which, like a gigantic octopus, extends a thirsty tentacle to every manufacturing plant on this continent, and whose fingers are slowly tightening their clutch upon your earning powers. The cost of power as a fixed charge in manufacturing is, therefore, a subject which now knocks at your door and demands admittance.

The cost of power is a subject which has gone so long without expert treatment by the average manufacturer that he has come to look upon his coal bill as an item of expense with which little or nothing can be done except pay it. I take it for granted that most of you are generating your own power in your own premises. That some of you are purchasing power from hydroelectric sources; and that all of you are interested in the question: "Can I produce my own power in my own premises at a lesser cost than it can be purchased for from the outside?" The manufacturer is in intimate touch with all his other departments. He knows exactly the outlay for advertising, and he employs the best of talent in this department. He knows exactly his costs of selling, and in this department he employs the highest ability within his reach. In fact, at the end of the year he knows the exact percentage which his advertising, his selling and his other departments constitute in the total outlay for the year. But as for power—beyond his coal bill and what he pays his engineer he does not know and, in my opinion, does not make a proper effort to know the exact cost.

A Concrete Example.

Since nearly every manufacturing plant which produces its own power is equipped with a steam plant, let us take as an illustration a moderate sized ordinary steam plant and let us assume that it operates on a basis of 10 hours per day for 300 days in the year, and that the average actual power required throughout each day of 10 hours is 200 h.p., and let us take coal at $3.50 per ton. It is safe to say that the coal bill for one year in such a plant will be not less than $4,200. That you will pay your engineer $1,000, a fireman $720, and after the incidentals have been added—for oil, packing, waste, etc.—the total will amount to $6,200. Then, interest and depreciation will easily bring this amount up to at least $7,000, or, say, $35.00 per h.p. for the average of 200 h.p.

It is probably safe to say that not one manufacturing plant in fifty is making its own power for so low a cost as $35. Now, let us see what this $7,000 per year as a fixed charge for power really stands for. Seven thousand represents the net profits on, perhaps, from $75,000 to $100,000 of finished product. It represents a fixed charge against your business—equivalent to $140,000 of 5 per cent. bonds, and it is needless to say that you would give much serious thought to the question of the issuance of such an amount of bonds. It is needless to say that you would analyze all the vital elements in your business before you decided to incur such a burden upon your earnings. And yet, you pay $7,000 a year for power, without having given anything like a corresponding consideration to the question as to whether or not $7,000 per year for an average of 200 h.p. is the right price.

Look only at the coal bill—of $4,200. Perhaps most of you do not know that of this $4,200 burned under your boilers, $3,800 are lost—absolutely non-productive: that out of every dollar's worth of coal burned, over 90 cents goes up the chimney and out of the exhaust, without doing any work of any kind.

If you contracted to pay a man a salary of $4,200 per year and should discover that the actual service he gave you was equal to only one hour out of each day, would you consider that good business? Or, suppose you owed $25,000 borrowed money and suppose you had to pay 17 per cent. interest on this money, would you consider that good finance? And yet, if yours is the average plant, I assure you that these are exactly the things which are happening in your coal bill.

It then becomes obvious that to get the cost of your power down to a point where the outlay in that department is consistent with the economies demanded in the science of modern manufacturing, you must either secure a reduction in the price of coal or you must generate your power on less coal than you are now consuming. The first alternative is out of the question, at least, so far as we can see. To materially reduce the amount of coal required to produce your present horse power is easily obtainable, if you will give this department the expert treatment which it deserves.

Horse Power Hour.

Let us now understand what one h.p. is. You hear on every hand "So much per annum per horse power," and "Cost per horse power hour." What is a horse power hour? If all the power in this little piece of coal could be utilized, if all its latent energy could be converted into actual work, it would lift 1,980,000 lbs. one foot high in one hour, or nearly 1,000 tons of dead weight off the ground for one hour. It weighs but 2¾ ounces, and yet could lift a weight twelve million times greater than itself. In other words, it contains the net equivalent of one horse power hour. But, when you undertake to convert this amount of latent energy into the actual driving of your machinery, I will not say that you must burn, but that you do burn, a piece this size (5 lbs.). It seems like a vast distance from this piece to that piece. But we cannot convert all of this latent energy into actual work, because nature demands a premium on what she gives us.

On the other hand, however, she does not ask us to pay any such price as this (5 lbs.) for one b.h.p. hour—this 17 per cent. interest. And since under modern methods we know that a brake horse power hour of actual work can be produced for a piece this size (2 lbs.), it certainly becomes apparent that in the average plant there is being burned, unnecessarily, and without return, the dif-

* Paper read before the Canadian Manufacturers' Association at Toronto, September 26th, 1907, by L. G. Read, Consulting Engineer, Montreal.

ference between 2 and 5 lbs., or 60 per cent. more coal than is required by refined engineering of to-day.

If 60 per cent. of this $4,200 coal bill can be saved, or, say, $2,500 per year, you may then consider that $2,500 per year saved is equivalent to your having retired an obligation of $41,500. Would you not consider a department worthy of expert treatment which unnecessarily places upon your business the equivalent of a $41,500 obligation at 6 per cent.?

Load Factor is Important.

If you will treat your power as a department and if you will give to that department the attention it deserves, you will easily confirm my claim that modern practice and actual results will place this great economy within your reach.

It would be impracticable, considering the limits of time on this occasion, and considering the great variety of local conditions, for me to undertake to detail the actual ways and means by which you may attain these ends; but, at least, I may say that you must approach this subject of power cost as a fixed charge in your manufacturing with a serious mind. You must ascertain what your load factor is. You must know what actual horse power it takes to drive your plant and when you know this you have got the key which will open the door to an important department in your business—a department which you have hitherto neglected.

To ascertain your load factor a diagram covering your daily run must be made by an expert. This diagram must show the h.p. output from your engines at every hour during the day's run and, preferably, for a number of days in succession, so that you may arrive at your load factor—that is to say, the maximum load and at what hour, the minimum load and at what time, and from these two you will obtain the load factor—the average actual h.p. you require. Then open a power account. Charge into that account that part of your capital invested in engines, boilers, pumps, dynamos, power house, chimneys, foundations, piping, shafting, belting and every part of your equipment which either generates or transmits power—together with all their accessories. This item will show you how much of your capital you have invested in your power department and upon it you will know what to charge for interest and depreciation. Charge into this account your fuel, engineers and firemen's salaries, oil, water, repairs, upkeep and all the incidentals which in the average manufacturing plant are lost in other accounts.

Some of you may say, "Yes, but all these items come out at the end of the year in some other account. So, what is the difference?" The difference is simply this: that in order to manage your power department in a way that will insure your getting your power at the right price, you must know all about that department—just as you know and insist upon knowing all about all the other departments in your business, and you cannot know all about your power department unless you follow it in this manner.

With the load factor known, and with all these items charged into this account, it then becomes merely a matter of dividing the total number of dollars footed up by the average h.p. taken from your power diagram—for one year—and the quotient will be your cost per annum per h.p.

It may not be for me to set down an arbitrary price per annum per b.p., as representing the price at which you would be justified in generating your own power instead of purchasing it from outside sources, but I will assume the responsibility of saying that unless you can purchase from outside sources —after charging interest and depreciation and everything which is properly chargeable to such motor equipment and appliances as may be necessary for you to utilize outside power—you must not pay more than $25 per annum per b.p. and only upon your average load and not upon your maximum load.

The Maximum Cost.

I will, however, place a limit upon your load factor; that is to say, your average h.p. requirement should be at least 60 per cent. of your maximum load. In other words, with a maximum of 100 h.p. and a minimum of 20 h.p.—or a load factor of 60 per cent in your plant, you would contract to pay $1,500 per year and no more. For, obviously, if it can be shown that you can produce your power on this basis, at this price, why should you pay a higher price than this for it from some outside source?

Whatever you may pay to outside sources in excess of this price, represents just that much dead loss in your business, and when you consider that a reduction in your fixed charges of even $2 per day is equivalent to your going to your bank and paying off $10,000 of outstanding 6 per cent. paper, you will realize that the earning power of money, like the latent heat in coal, is fraught with great possibilities, when given the proper treatment.

Now, let us take the point of view of the power company that sells its power as a public utility. Some think that the development of water powers will solve this great problem of power cost. But, if you will look closely, you will find that the limits of these possibilities are soon reached. In the first place, water powers are not always located where we want them, and where we need them. Let us take a hypothetical case. Suppose we develop a water power with a maximum of 100,000 h.p. Our total investment will amount to at least $65 per h.p. initial cost, or, say, $6,500,000.

We contract to deliver power to thousands of users. Our whole equipment is designed and installed, with all our transmission lines, our transforming stations; with all the local equipment required at points of destination; our management and our organization are based upon $6,500,000 actual investment. We will say that our peak load; that is, the top notch of our output each 24 hours, reaches the 100,000 h.p. mark. It is safe to say that the load plot—that is, a diagram showing the horse power output at each hour during the 24—will average not more than 40,000 h.p. In other words, the total amount of power we sell equals a load factor of 40 per cent.

Now, 40,000 multiplied by $65 per h.p. (initial cost) equals only $2,600,000, and you will see at once that the price which must be charged per annum per h.p. must be an amount sufficiently high so that an average output of 40,000 b.p. (or $2,600,000 of our investment) will earn a return sufficient to carry the entire $6,500,000. And this is the condition which usually prevails when a water power is developed and expanded into a public utility.

On the other hand, if a water power is developed for local use, by an individual concern; obviating the necessity of long transmission losses and the low average h.p. output, you will readily see that, under these conditions, water power serves its best and most practicable purpose. The ten best water power developments in the world—including the cheap water powers of Canada—show an average cost of $10 to $12 per annum per h.p. This is cost—not the price at which the power is sold. Suppose, after allowances for transmission, transformer losses, fixed charges and a fair profit, it were delivered to the consumer for $20 per h.p. on the usual flat rate basis.

You contract to pay for a certain amount of power whether you use it or not. (Say 100 h.p.) At the end of the year you will find that since your own load factor will probably not average over 60 per cent. (for you, as well as the big power company, have your peak load and your minimum load, and, consequently, your average horse power requirement), what you have actually paid for what you have actually gotten equals $33.33, instead of $20. Because

—$20 multiplied by 100 h.p. equals $2.000, and $2,000 divided by your actual average load of 60 h.p. equals $33.33 per h.p.—or 65 per cent. more per annum per h.p. than the rate named in your contract. In other words, you pay the power company (60 h.p. × $20) $1,200 for power you do get, and $800 for power you do not get.

Some Comparisons.

The gas company—a public utility—charges you for the exact amount of gas you use and no more. The water company—a public utility—does the same. Now, when a power company elects to expand itself into a public utility, on what theory has it the right to demand this premium of $800, this 65 per cent. for something it does not deliver? Is it because "the power is there, if you want it"? Then, so is the gas "there if you want it"! So is the water "there if you want it"! Is it because of the power company's low per cent. of load factor? Then why have not the gas company and the water company an equal right to make the consumer pay the difference between their average output and their maximum capacity?

The answer is that the sale of power as a public utility is a new enterprise. The consumer has overlooked the importance of this department. Hence the power companies make hay while the sun shines. But there are exceptions; where the average load factor in a plant is equal to and more than the minimum amount of power contracted for; but these exceptions are few, and you will find that a public power company avoids such contracts.

The Key to the Power Question.

Now, just one final word. The key to this whole question is the load factor—the average actual h.p. required throughout the day's run. Do not confound this with your maximum h.p. requirement. When you talk of "so much per h.p. per annum," I insist that it be based upon the average h.p. and not the maximum rating. And I insist that with a load factor of 60 per cent. it should not cost you—whether you make it yourself or purchase it from the outside—more than $25.

Make up your minds now that you will make a department of your power; that you will open a power account; that you will study this question, and if you do these things, the small expense involved will come back multiplied tenfold, as profit.

I am indebted to the officers of this association for the opportunity of even presenting so briefly the principal claims which I think the question of power has to the consideration of manufacturers.

Since, however, justice cannot be done to so broad and so important a subject within such time limit, I shall be glad to send to any member of this association, more explicit details by which he may be guided in making a department of his power and the giving to that department the attention which, in this day of refined engineering, is easily within his reach.

Welding by Thermit

The Stern-Post Shoe of the S.S. Corunna Successfully welded.

An interesting experiment and one that marks the progress of Canada, was the steel welding process that was tried for the first time in Canada on the steamer Corunna. This vessel plys between Montreal and the Upper Lakes, and had her rudder post and shoe broken recently in an accident in the Cote St. Paul Locks. It was successfully mended without removing the broken parts and the work was watched with great interest by a large number of shipping men, as the success attending the demonstration was of great importance to marine repairing in Canada. A comparison of the two methods of repairing will show the saving in the repairs to the Corunna. Under ordinary circumstances, the owners would first have to undergo an expense of $1,000 in having the steamer towed to Cleveland before commencing the work of repairing. Both time and expense were thus saved, and, in future, work of this character instead of going to United States, as formerly, will be done in Canada. The method is marvelously simple, as is shown in the accompanying illustrations. Fig. 1 is a view of the broken stern-post shoe of the s.s. Corunna before welding.

Fig. 1—A view of the fracture of the S.S. Corunna's stern-post shoe before welding.

Fig. 2—The stern-post after the welding process by Thermit was concluded.

The parts to be welded were thoroughly cleaned, a wax pattern was made over the broken parts, and then a mould was built around the shoe, a hole being left in the bottom of the mould to allow the wax to run out, leaving the space for the molten steel. A powerful gasoline torch was inserted, and brought the broken parts to a red heat. As the wax melted it flowed out the hole in the bottom of the mould, and the opening was then closed up. In the meantime, a sheet iron shell crucible was swung over the mould and the charge of thermit powder placed in it. A teaspoonful of ignition powder was placed on top of the thermit in the crucible, and ignited with a match. In thirty seconds the crucible was full of molten steel at a temperature of 5,500 degrees Fahrenheit. A hole was then tapped in the bottom of the crucible, allowing the steel to flow into the mould. The superheated thermit steel fused the broken parts together, making the shoe as strong as before the break. Fig. 2 shows the stern-post shoe after the welding was concluded. Mr. William Abbott, agent for the Goldschmidt Thermit Company, New York, undertook and successfully completed the repair of the broken stern-post shoe.

You cannot learn more than you now know without venturing something that you have not tried.

To underpay or overwork men is to deprive them of facility, time and repose for self-improvement. We create ignorance, we put a brick in their hands to throw at our heads.

Bearings and Their Lubrication

Overcoming Friction in Bearings and Their Design.

By JOHN EDGAR

The bearing is one of the machine elements that we meet on every side. They are absent only in few instances. It is hard to conceive of a machine that has no bearings. In the strict technical sense a bearing is any area that takes a pressure or carries a load. In this article we shall restrict the term to those cases where the bearing carries a rotating journal or is a rotating member itself, and is supported by a stationary journal. A bearing in machine design is the internal surface of the cylindrical housing for the journal. The journal being the shaft or other cylindrical object that rotates in the bearing.

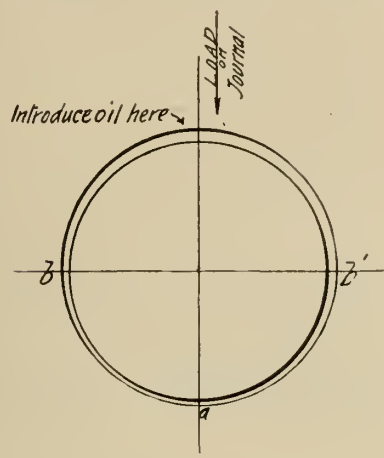

Fig. 1—Greatest Pressure at Lowest Point.

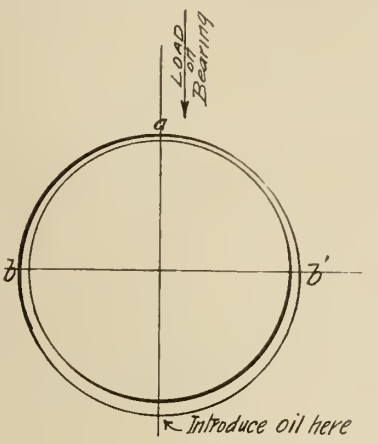

Fig. 2—Greatest Pressure at top.

The friction caused by the movement of one surface upon another is the cause of most of the trouble in the operation of machinery, that is due to the bearings. The object is to reduce this friction as much as possible, and in properly designed bearings this friction is reduced to a minimum, the load per square inch of the projected area being such that experience has shown can be used without causing the bearings to heat and seize the shaft. Lubrication is necessary, and, in most cases, is accomplished by introducing between the surface of the journal and that of the bearing oil, grease or other lubricant. The pressure per square inch that a bearing will stand depends on the lubricant and its method of introduction. The object of the lubricant is to separate the surfaces as much as possible, and thus reduce the friction to a minimum. Were it possible to produce surfaces that were absolutely smooth the movement of one such surface upon another would not cause friction, therefore trouble would not be experienced and a lubricant would not be necessary. It is one of the offices of the lubricant to fill up the hollows in the imperfect surfaces and thus produce a good substitute for the perfectly smooth surface. It is obvious that any pressure sufficient in extent to squeeze the oil or grease out from between the surfaces must be avoided. For this reason heavier oils and the greases are used where the heavy pressures have to be carried at moderate speeds. Should the heavier lubricants be used in fast running light bearings the friction of the lubricant within itself would be excessive, so that for this class of bearing a lighter weight oil is necessary.

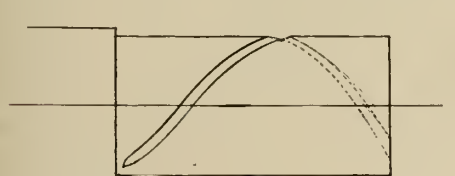

Fig. 3—Spiral Oil Groove.

Bearings Design.

The proportion of the bearing with respect to diameter and length is generally made as follows: For hangers, supporting line shafting, when the bearing is self aligning, the length is made about four times the diameter of the shaft. When, however, the bearing is not self-aligning, as in the case where the bracket and bearing are cast in one piece, or the latter bolted to the bracket the diameter should be only about one-half as long, being about two diameters in length. The reason for so shortening the bearing in the latter case is to reduce the pressure at the end of the bearing, due to the deflection of the shaft which causes no harm in a box that is self-aligning, because the latter adjusts itself to the general deflection and takes a position tangent to the elastic curve; in the former case, however, bending of the shaft causes it to bear harder, and with more pressure at the edge near the load, because the centre line of the box cannot adjust itself to the general direction of that of the shaft, therefore the length must be shorter in order that the pressure may be better distributed over the whole length.

Other bearings, for uses outside of the supporting of line shafting, are so designed that the pressure per square inch of the projected area does not exceed certain prescribed amounts. These pressures range from 15 lbs. to 600 lbs. The former pressure is used in the design of line shafting bearings of cast iron, and is rather a small value, while the latter is found in examples of steam engine bearings, where the journal runs slowly. Sixty pounds pressure is a good figure to use when space and conditions

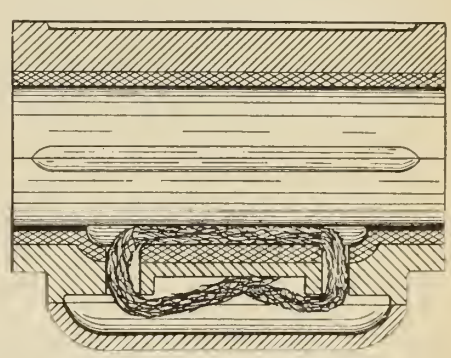

Fig. 4—Wick Oiling Bearing.

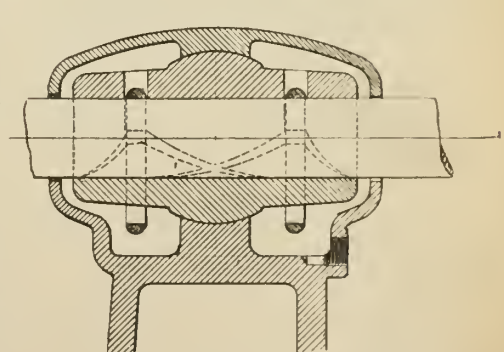

Fig. 5—Dynamo Ring Bearing.

will permit, and may be run up to one hundred pounds without any serious results.

Applying the Lubricant.

The pressure that a bearing will stand depends much on the manner in which the lubricant is applied. A bearing properly proportioned and all right as to

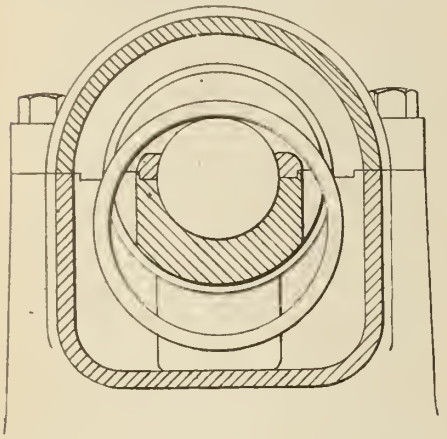

Fig. 6—Cross Section of Dynamo Ring Bearing.

design in other respects, may act badly from lack of consideration on the point of lubrication. The application of the lubricant is then as great in importance as the general design of the bearing. The same bearing when inadequately lubricated has been known to seize at a pressure of 300 lbs. per square inch, when altered and oil applied by an oily pad the pressure permissible before seizure was raised to over 500 lbs. The introduction of the oil by means of small oil holes or cups is a very unsatisfactory way of lubricating a bearing and should be used only in cases where the bearing is subjected to very light pressures. Oil should never be fed into the bearing at the point where the load is heaviest, but at the point where the pressure is at a minimum. When an attempt is made to introduce

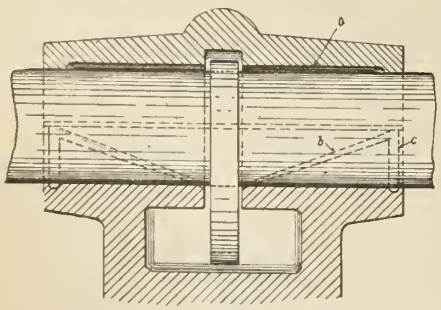

Fig. 7—Single Ring Bearing.

the oil at this point, the bearing is only oiled at times when the load reaches a minimum, or zero, or when the bearing is stationary, because the pressure of the oil between the surfaces at that point is greater than that in the reservoir, so that it is impossible for the latter to enter the bearing under those conditions. It has also the bad quality of allowing a vent for the escape of the oil that is already between the surfaces, so that the result is worse than bad. The above point is shown by Figs. 1 and 2—Fig. 1 represents a bearing in which the greatest pressure occurs at (a) the lowest point this pressure gradually decreases until at the horizontal diameter (b, b¹) the pressure becomes zero, and is zero at all other points in the circumference. The lubricant in this case should be introduced at the top as indicated, where it has a chance to enter and is carried to the effective point by the motion of the shaft. Fig. 2 shows a similar bearing, but in this case the bearing carries the load and the greatest pressure then comes at the top and the oil should be introduced at the bottom.

It is the general practice to groove the bearings carrying the groove along the bearing nearly the full length. This groove is invariably cut at the point (a) and acts as a vent for the oil to escape, by thus defeating its purpose.

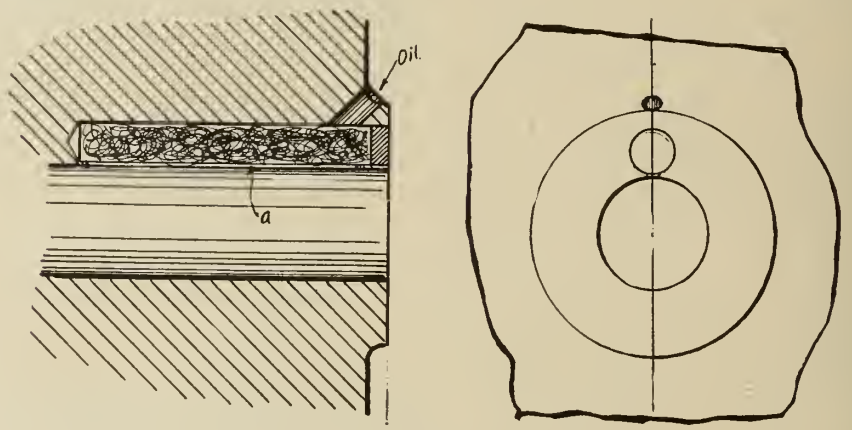

Fig. 8—Special Bearing with Reservoir.

The proper place for the groove is at the point of introduction of the lubricant and at the points (b and b¹) where they act as reservoirs and are then very serviceable. It is sometimes the practice to groove the journal. The groove shown in Fig. 3 in this case being cut spirally around the shaft forming one continuous groove. For slow running journals that have to carry a considerable load it is a mistake to groove them in this manner. The groove in this case acting as a vent and also carrying off the oil instead of holding it in its proper place. For fast running shafts, it is good to groove them spirally, because the pressure on such bearings is generally light and the groove in that case keeps a fresh supply of oil on the whole surface.

Where the load is intermittent, as in the case of presses and such machinery, and where it is first in one direction and then in the other, as on the crank pin of a steam engine, the lubrication is more perfect and the siphon feed will be more effective.

Special Oiling Devices.

Fig. 4 shows a bearing fitted with a wick oiling device. In this case the oil reservoir is in the cap and the wick is threaded through the holes in this cap and in the groove provided for it. As long as there is any oil in the reservoir the wick will, through the aid of capillary attraction, feed it to the shaft which it wipes. It will be noted that this bearing is lined with a bearing metal.

The high speeds and continuous running necessary in the cases of the dynamo and motor, have been responsible for an entirely new form of bearing, that, the ring oiling type. In this type the bearing is lubricated by oil carried onto the shaft by a ring which rolls on the shaft and through a reservoir of oil from which it carries oil and deposits it on the shaft at the point where it comes in contact with same. Fig. 5 shows a longitudinal section through the pedestal of a dynamo fitted with such a bearing. It will be noted that this bearing is of the self-aligning type. The shaft being oiled by two rings, the oil is distributed in all directions by the grooves. Provision is made for drawing off the oil spent in vitality, and also means for replenishing the supply. Fig. 6 shows a cross section through the same bearing.

Fig. 7 shows a single ring, ring-oiling bearing, made solid with the pedestal. The reservoir is cored out under the centre of the bearing, a slot opening into it in which the ring runs. In this type bearing where the supply of the lubricant is so steady, and plentiful precaution must be taken to hinder the oil from flying about as it runs out at the ends of the bearing. The design shown in Figs. 5 and 6 takes care of this by having the bearing encased in

the covering shown. But in that of Fig. 7 no such easing is provided. To stop the oil from flying the grooves (e) are cut in the lower half of the bearing at the ends. These grooves catch the oil and the groove b leads it to the reservoir. The groove a distributes the oil along the length of the bearing. The ring oiler is the highest type of modern self-oiling bearing, and is being applied to many varieties of uses, notable among which is that of countershafts and line shafts.

Lubrication under pressure is also being developed to a certain extent, especially in engine and kindred work. Here the oil is forced into the bearing by the aid of a pump. The oil being used over and over again, and a fresh supply is thus continually fed into the bearing. Sometimes a bearing that gives trouble can be made to work satisfactorily by doing as suggested in Fig. 8. Here a hole of considerable size is drilled into the metal surrounding the bearing as close to same as can be drilled without breaking through. A slot (a) is then cut connecting the hole with the bearing. An oil hole is then drilled into the hole from the outside. The large hole is filled with felt or waste and the end plugged. This forms a good reservoir for oil and gives a constant feed to the bearing. Vertical bearings that are bored out from the solid frame can be oiled by this method the hole running along the bearing in the vertical position and the feeding being done from the top.

Machine Shop Cost System

A Simple Cost System That Is Efficient.

Machine shop superintendents and cost keepers are constantly on the lookout for a simple and efficient cost system. For the benefit of those readers of Canadian Machinery we give below a description of the system employed by the Bawden Machine Tool Co., Limited, Toronto. F. M. Bawden has realized that simplicity and efficiency are the chief features of a cost system and with that idea, designed his time and cost cards. We have reproduced those used in his cost system.

When an order comes to the works for a certain number of engines or engine parts, card No. 1 is filled out. To illustrate, we will take a concrete example: "Order from," Gas Engine Co., Toronto; "Order No.," 285; and under "Description of order" is written, Gas governors—6 wanted. Drawings G—18-21. A copy of this order is then sent to the foreman, who issues cards similar to Fig. No. 2, which would be filled in as follows:

Job sheet for Gas Engine Co.
Employe's No.—35.
Job No.—285.
Drawing No.—G-20.
Name of part.—Ferrule.

Under operation is written boring or whatever the operation may be and the number of pieces, and opposite this the workman fills in the number of hours he is on the work each day. Before starting to work on the castings they are weighed and under material is written the number of pounds of material used. Suppose a man was turning ferrules and it took him four hours on Monday, nine on Tuesday, and five on Wednesday, he would have a total of eighteen hours, or, dividing by six, it takes three hours to turn each ferrule. In the same way may be had the weight of each ferrule. A workman gets only one of these cards at a time. He must hand in one card before starting another job, and a card is given out for each operation done on each part, thus there is a card for drilling, boring, turning, etc., for each part going to make up the machine. If a duplicate order comes in, then, by looking up former cards, the foreman knows at once how long a job should take, and if more time is being spent on the work than in the first case, he can at once look into the matter and find out the cause. Then, too, if he thinks he can improve on the time, on some of the work, he can experiment and find a means for simplifying the work amd increasing the working capacity of his mechanic.

When the cards are returned to the office the items on card No. 1, date, hours, rate and amount, are filled in from card No. 2, and the amount of material, with its cost, is filled in so that the superintendent can tell at a glance the exact cost of each part or the total cost of each order going through the shop. Very little clerical work is required in this system, and it is found to give all the desired information. No. 1 cards are filed according to the order number, and No. 2 cards are filed away alphabetically, thus the cards we have described come under G. They are there arranged according to drawing numbers, so it is an easy matter to use them for reference. It is, therefore, obvious, that while simple, this system is complete and all the details are under the direct notice of foreman, superintendent and cost-clerk.

TURRET FOR ENGINE LATHE.

By J. H. R., Hamilton.

The turret attachment shown in the illustration can be placed on any engine lathe and will greatly add to its output of nuts and screws or any other small fittings made from a bar. It can also be used for small castings requiring the operations of turning, boring, drilling, or tapping.

A is the main spindle (in the form of a crank shaft) fitted in the tail-stock, with (a) as the crank or centre piece for turret B.

B is the turret which revolves on (a) and contains as many holes as are desired.

C, C, C, are cams which revolve the turret by contact on roller R.

D is a bracket bolted to tail-stock carrying trip T, and roller R.

E is a lock pin place in flange of A and held in position by spring S.

F is a lever to release pin E.

G is a movable piece held in position by spring S, and revolving on pin P.

B is a shell to keep turret B in position and fastened to B with screws, I, I.

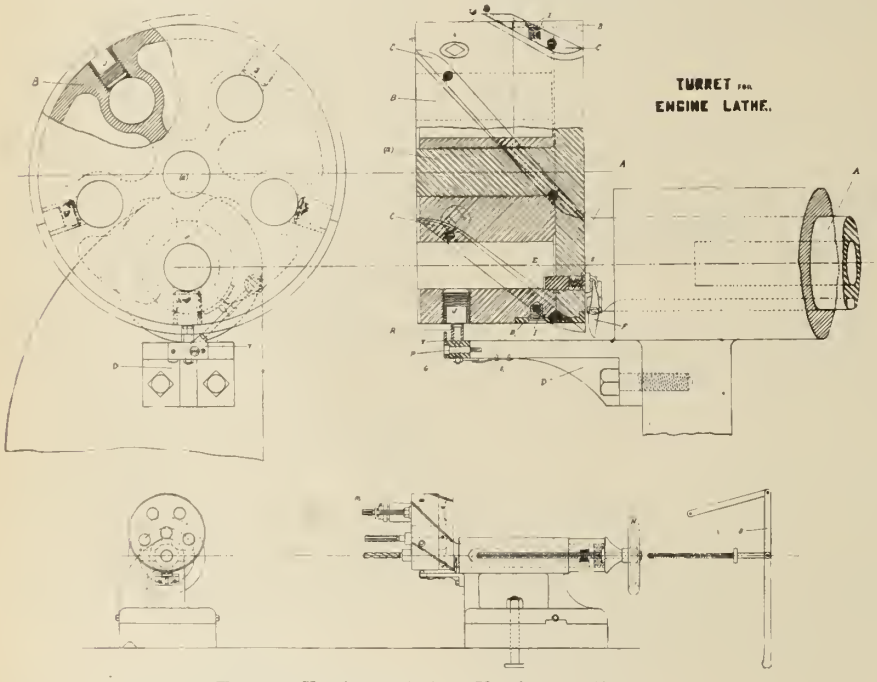
J, J, are screws to lock tools, etc., in turret.

R is a roller bolted to D.

T is a trip to release pin E.

Arranging tools in turret to suit work and chucking work by gauging with stop M, turret is taken back by hand wheel N (or for light work, lever O); lever F comes in contact with trip T, releasing pin E, cam strikes roller R, revolving turret to next position, and then advances for next operation, roller R passing next cam by piece G swinging on pin P; operation is completed and continued as before. Suitable stops could be arranged so as to insure duplicate work.

Piece B could be cored out as shown to avoid weight.



Turret Equipment for Engine Lathe.

HOLDING DEVICE FOR TRIANGULAR RULES.

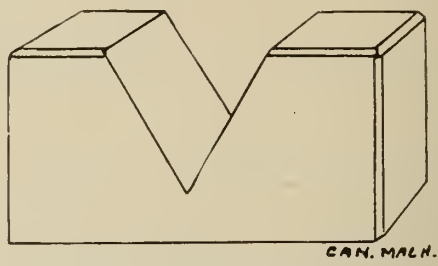
By a Draughtsman.

The accompanying sketch shows a block I have used with a triangular rule and found a great convenience. Each time I laid down the rule I would lose the particular scale I was using, whether 1-8, 1-16, 1-32, 1-64, etc. By taking a small block of wood about two inches long and one inch high and cutting a V-shaped hole to conform with the shape of the rule, as shown in the sketch, I could keep the scale always before me and use a pair of dividers without any waste time.

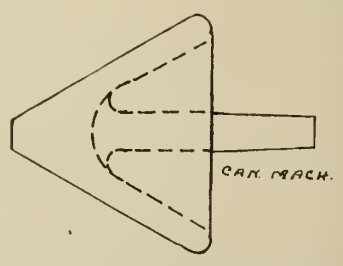
LATHE DEVICE FOR THREADING PIPES.

By A. E. D.

Considerable difficulty is often encountered when a pipe is to be threaded or cut in a lathe. One end is put in a chuck and a board or wooden plug is fastened in the end to be threaded and a rest is used to keep the pipe running true. Anyone who has used this arrangement knows how very unsatisfactory it is and how long it takes to set up a pipe. In our illustration we show a device which we think will save time and obviate the trouble. This has been used in several shops with success. It is a self-centre made of cast iron and the size depends on the size of the pipe to be threaded, but one centre will accommodate a great number of sizes of pipe. It is a cast iron cone with a spindle, turned to take the place of the centre in the tail-stock, and the outside face of the cone is machined. In small sizes the centre is cast solid, but for the larger size pipes, where a large centre is necessary, it can be lightened by casting it with a hollow centre, as shown by the dotted lines. If it is thought that more strength in the centre is required, it can be cast with webbs. By means of such a device a pipe can be easily and quickly centred for cutting or threading a pipe in a lathe.



Holder for Triangular Ruler.



Lathe Centre for Threading Pipe.

THREAD GAUGE.

By James C. Moore.

A simple, but very handy tool, is a thread gauge with bevel attached for setting the cutting tool to the required angle, clearing the rake of the thread while cutting coarse pitch. The rake of

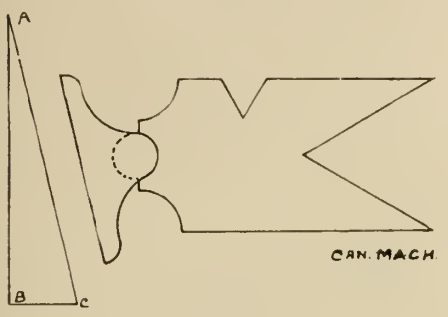


Fig. 1—Setting Gauge.

the thread is obtained by a piece of paper or tin placed around the circumference to be threaded and cut the exact length of the circumference and as wide as the pitch to be cut. This is shown in Fig. 1: A, B, is the line of circumference B, C, the pitch line, and

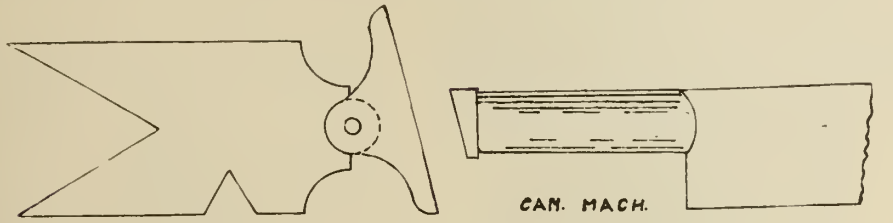

Fig. 2—Setting Tool for Nut.

the line A, C, is the rake of the thread. The bevel piece of the gauge is set to this line and the tool is placed on toolholder to clear. Round steel will be found most convenient, as it can be placed at any level to suit rake. If flat or square steel is used the tool must be ground to suit. This tool is particularly valuable in cutting a nut. The accompanying illustrations show the use of the thread gauge. Fig. 1 shows the rake of the thread and the method of setting the gauge. Fig. 2 shows the manner of setting the tool to thread a nut.

GRINDING FRAME FOR LATHE.

Herewith is a grinder frame designed to be placed on the carriage of a lathe, the work being held in a chuck, face plate or by other means. It does heavy grinding with good satisfaction. It is simple in construction, very strong and rigid. It has adjustable bearings, and is absolutely dust proof.

The frame can be secured to the lathe carriage in any position or, as shown, with open end of box frame up so as to allow the belting from above. The box frame, Figs. 1-2, is a plain box finished all over outside and recessed as shown to receive bearing yoke. The yoke is of cast iron bored to receive bronze bushings, the outside turned and threaded to receive brass adjusting nuts. The pulley is also of cast iron. A fibre washer is put between pulley ends and bearing yokes. A dust proof collar, A, is secured with headless screw. A full size end of shaft is given in Fig. 3, showing taper end, also wheel bushing and clamping collars. We have in use other grinders, but this serves the purpose the best.—Machinist, in Modern Machinery.

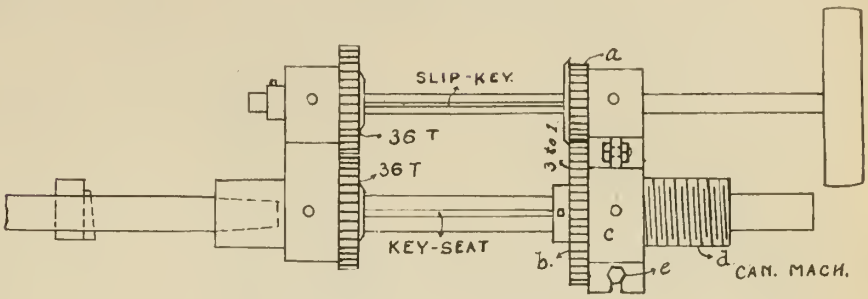
ERRATA.

In the article, Taper Turning, by J. H. R., Hamilton, on page 42 of our October issue, the example in the third paragraph should read: "The taper is three-quarter inches per foot, move tail stock over $\frac{3}{8}$ inches per foot.

A QUICK AND ACCURATE BORING MACHINE.

F. A. Bawden.

The illustration shows a plan of a boring and facing machine used by the Bawden Machine & Tool Company, Limited, Toronto, for the machining of their drill presses. This boring machine is bolted to a planer and the drill press rests on two V-blocks, which are securely bolted to the planer bed to which the

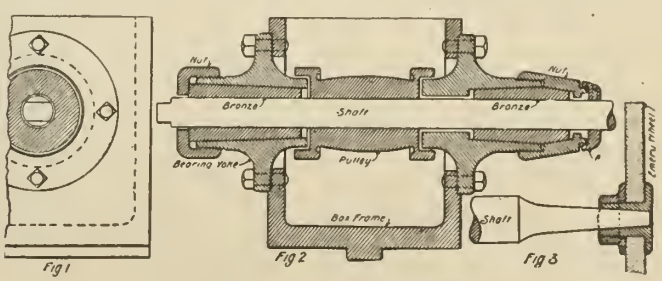


A quick and accurate boring machine.

drill press is also bolted. The tool is in a shaft, as shown in sketch, and the spindle works in two babbited bearings fastened to the planer. Vibration is thus eliminated and the whole arrangement is fool proof. All the operation of boring, facing and babbiting are done on the planer. The drill press is thus handled only once, and the facing of the holes at right angles for the gears are made absolutely squared with the bore. Gear a is for throwing the drill in and out of gear. When facing, this gear, which runs on a slip key, is pushed forward and the facing shaft is turned by hand by means of a special wrench used on the gear b. The gear b and feeding sleeve d are in one piece and work in a keyseat in the shaft, c is a bearing threaded in the top only so that when the cutters feed up to the limit, by loosening bolt e the bearing c is lifted upon a hinge and the sleeve pushed back. The collar in front of the gear b is fastened firmly to the shaft. The power is obtained from a countershaft above the planer, and a quarter-turn belt transmits the power to the driving pulley.

Mr. W. H. Munro, of Peterboro, has joined the staff of McDougall & McRae, consulting engineers, Ottawa.

Mr. J. W. Smith, C.E., of the firm of Galt & Smith, Toronto, and Mr. R. S Lea, C.E., of Montreal, have been appointed to investigate and report on a sewerage system for Regina.



Grinding Frame for Lathe.

Developments in Machinery

Metal Working **Wood Working** **Power and Transmission**

A NEW LIFTING MAGNET.

After much experimenting and many severe tests, there has been placed on the market a lifting magnet that is meeting with success. Most of the features in the design are original, but the fundamental principle is that of any ordinary magnet, a steel core and coils of wire to carry the exciting current.

Wherever pig iron, metal plates, tubes, rails, beams, scrap or heavy castings of iron or steel are handled, lifting magnets can be advantageously employed. There is no waste time adjusting block and tackle to the object to be lifted. For lifting scrap and pig iron the lifting magnet is of special service. The magnet is lowered onto the piles of scrap or pig iron and without any further work of handling the iron, it is lifted onto or from the cars, as the case may be. In foundries and rolling mills, magnets are useful for lifting and transporting metal too hot to be touched with the hands.

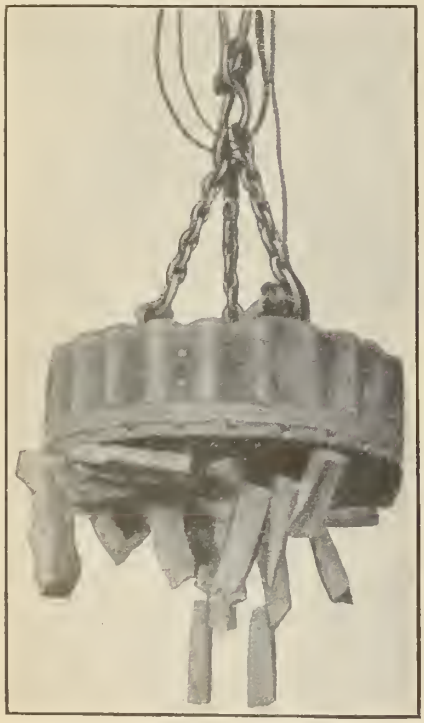


Fig. 1—Lifting Pig Iron.

Lifting Capacity of Magnets.

The lifting capacity depends to a great extent on the nature of the material to be handled. A 50-inch magnet, under favorable circumstances, will lift as much as 20,000 pounds, but under more adverse circumstances the lifting capacity might drop to 1,000 pounds, or even less. In one test, a 52-inch magnet readily picked up a steel skull weighing 5,500 pounds, and this in spite of the fact that the surface presented to the magnet was very uneven and extremely dirty, being partially covered with slag.

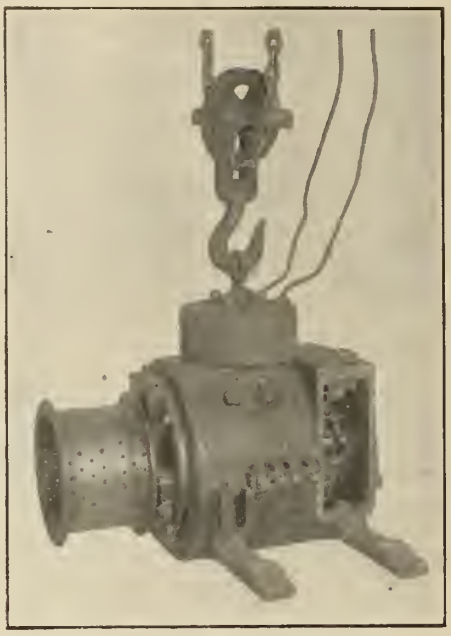

Fig. 2—10-inch Magnet Weighing 75 lbs. Lifting 800 lbs.

Fig. 1 was taken during a test at the Carnegie Steel Co.'s Donora works, when a 52-inch magnet lifted from the ground 32 sand-cast manganese iron pigs, averaging 65 pounds each in weight, making a total lift of 2,080 pounds.

Weight and Construction.

A 10-inch magnet weighs about 75 pounds, and Fig. 2 is a view of one of these small magnets lifting a Bliss Electric Car Lighting Generator weighing 800 pounds, or over ten times its own weight. A 50-inch magnet weighs about 5,000 pounds. The construction consists of a hollow steel casting in which the magnetizing coil, on the design and construction of which the efficiency of the magnet depends, is placed. The coil is most carefully built up of alternate layers of copper and asbestos, and is insulated from the cast steel frame by thick sheets of mica. There is no danger of the magnet being damaged if, by accident, it should be left in the circuit over night. Under test, these coils have been heated to 470 degrees F., without injury. It will be noticed by reference to Figs. 1 and 3, that the frame of the large magnets is corrugated. This construction provides a greater surface for heat radiation and at the same time forms niches to protect from injury the heads of the through bolts which fasten the removable pole piece to the magnet frame. To aid the heat radiation, the magnet frame has a central aperture through which the air circulates freely. This opening reduces the weight of the magnet and prevents the hot air from forming in the concave under the surface of the magnet. In lifting plates with plain surfaces this concavity becomes objectionable owing to the fact that an air gap intervenes between the inner pole and the object to be lifted. This is overcome by inserting in the central aperture an auxiliary pole piece so proportioned as to extend downward to the level of the outer pole, thus insuring intimate contact of both poles when an object is being lifted. Another feature worthy of note is the through bolts which are used to secure the pole

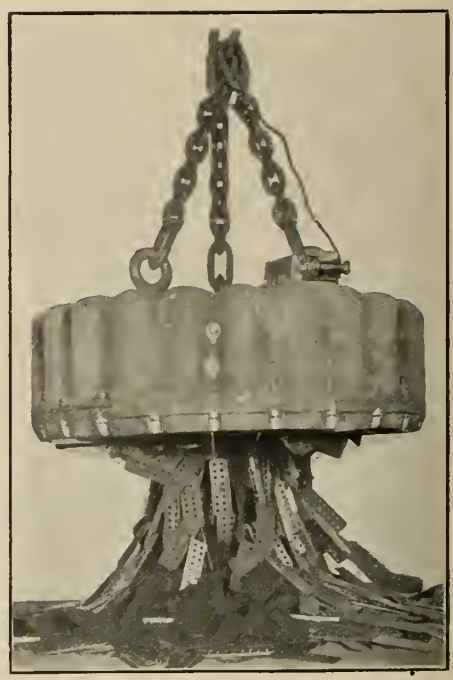

Fig. 3—Magnet Handling Steel Stampings.

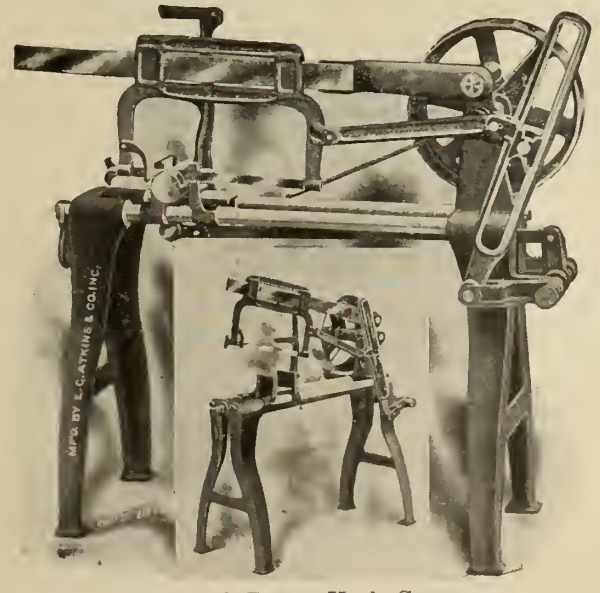
shoe to the magnet frame. These are used to overcome the difficulty sometimes experienced with cap screws that have rusted in, for if a through rod becomes rusted, it is an easy matter to chisel off a nut and knock out the through bolt. It is thus a comparatively simple matter to replace a pole shoe, should it wear out. The removable pole shoe is clearly illustrated in Fig. 3, in which the magnet is shown handling steel stampings. In this case the magnet was not lowered into the stampings, but was brought to within about three feet of them, when the perforated steel plates rose to the magnet as shown in the illustration.

Magnets such as we have described are manufactured by Cutler-Hammer Clutch Company, Milwaukee, Wis.

NEW POWER HACK SAW.

A new power hacksaw has just been placed on the market, called Kwiv-Kut on account of its quick cutting ability. An adjustment on the saw arm allows the saw-blade to be used from end to end. A feature of the machine is the quick-return motion after cutting. The arm connects the saw by means of pin joints at either end. A cross-head runs on ways in the lever, and as the return motion begins the cross-head is at the lowest end of the ways. The leverage is thus very short and a quick-return is the result. The return stroke is three times as fast as the forward stroke.

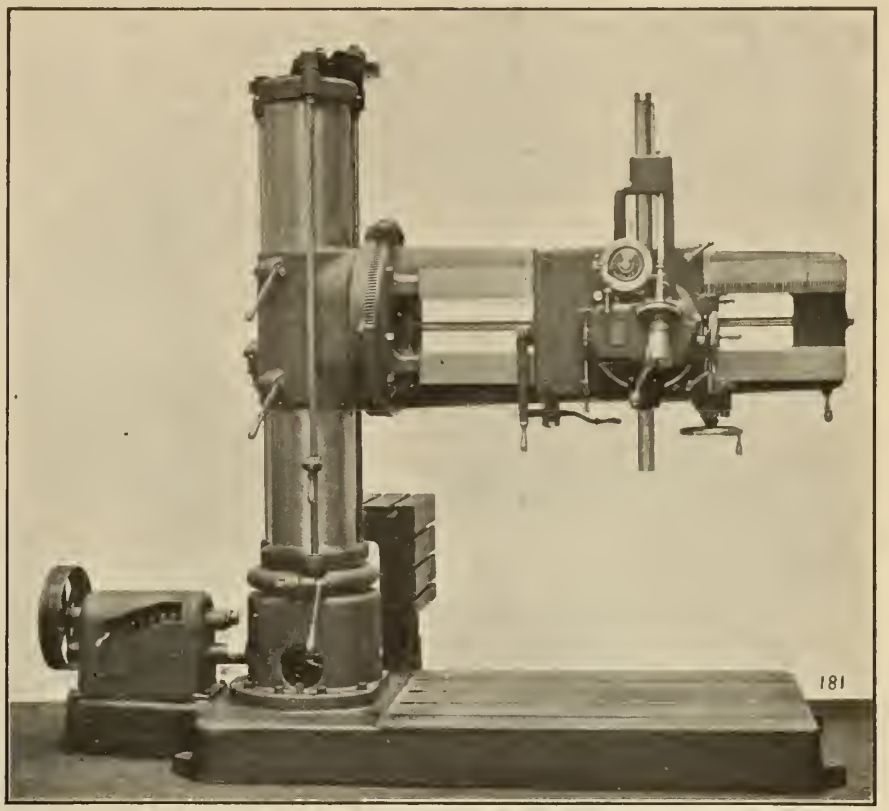
It is constructed on strong mechanical lines and the machine automatically adjusts its stroke to all sizes of cuts. It is absolutely automatic, being equipped with an attachment which throws a clutch and stops machine as soon as the cut is made. The saw frame is mounted on babbited bearings. The frame may be thrown back, leaving the vise absolutely clear. Hand-power may be used if desired. A split finger holds the blade in perfect alignment.



Improved Power Hack Saw.

A No. 2, with capacity 5x5 inches, uses a floor space 36x17 inches, a blade 14 inches long, a pully 14x2½ inches, runs at 50 revolutions per minute, and weighs 180 pounds.

This power hacksaw is manufactured by E. C. Atkins & Co., Indianapolis, Indiana.



A New Universal Radial Drill.

The construction is simple. A friction clutch is used for applying power, a feature used in the saw we here illustrate. The vise is equipped with right and left-handed screws, and holds work firmly. It is manufactured in three sizes and will accommodate cuts up to 8x8 inches.

NEW UNIVERSAL RADIAL.

The chief characteristic claimed for this machine by its makers lies in the design of the arm which offers great resistance to the combined stresses of twisting and bending. This feature, combined with the exceptional facilities which the open form of arm offers for the introduction of a driving mechanism commensurate with the strength, power and durability obtainable in the balance of the parts, marks a most noteworthy advance in universal radial drill construction, containing, for the first time in its history, a degree of efficiency equal to that of a plain machine.

The sleeve is mounted on a stationary stump which extends up to and has a bearing at the top of the machine. This is equivalent to a double column, and affords that stiffness which is so essential to true work. The arm may be rotated through a complete circle on its girdle and the head through a complete circle on its saddle, which permits drilling at all angles radiating from the centre of a sphere. The back gears, which are located back of the saddle, and may be engaged or disen-

gaged from the front of the machine while running, furnish three changes of speed, each of which exerts at the spindle more than two and one-half times the pulling power of the next faster one. The spindle has fifteen changes of speed with the cone drive and twenty-four with the gear drive, and is provided with both hand and power feed, quick advance and return, safety stop, automatic trip, dial depth gauge and hand lever reverse. An engraved plate attached to the speed box shows how to obtain the proper speeds for different diameters of drills.

The depth gauge answers a double purpose: besides enabling the operator to read all depths from zero, which does away with the usual delays concomitant to scaling or calipering, it supplies a convenient means for setting the automatic trip, the graduations showing exactly where each dog should be located in order to disengage the feed at the desired points. The automatic trip operates at as many different points as there are depths to be drilled at one setting of the work; in addition, it leaves the spindle free, after any intermediate tripping, to be advanced, or raised and advanced, or traversed its full length, without disturbing the setting of the dogs; it also throws out the feed when the spindle reaches its limit of movement. The feeding mechanism furnishes eight rates of feed, ranging in geometrical progression from .007 inch to .064 inch per revolution of spindle, each of which is instantly available, eliminating all loss of time incident to shifting a belt, or to operating under a feed of unnecessary fineness. An engraved plate attached to the head shows the operator how to obtain each of the feeds. The tapping mechanism is located on the head, and permits the backing out of taps at any speed with which the machine is provided, regardless of the speed used in driving them in. It is fitted with a friction clutch operated by a lever, the handle of which extends around under the arm within convenient reach of the operator. The driving mechanism is incased in a box made fast to the base of the machine, and consists essentially of a pulley, a cone of seven gears, a ratchet, a ratchet gear and operating lever, the mere shifting of which from one notch to another furnishes any one of eight speeds. This box, taken in connection with the back gears on the head, gives the operator a choice of twenty-four carefully selected speeds, each of which is instantly available. The machine is furnished as either a half or full universal, each of which styles is made in three sizes, 4, 5 and 6 feet.

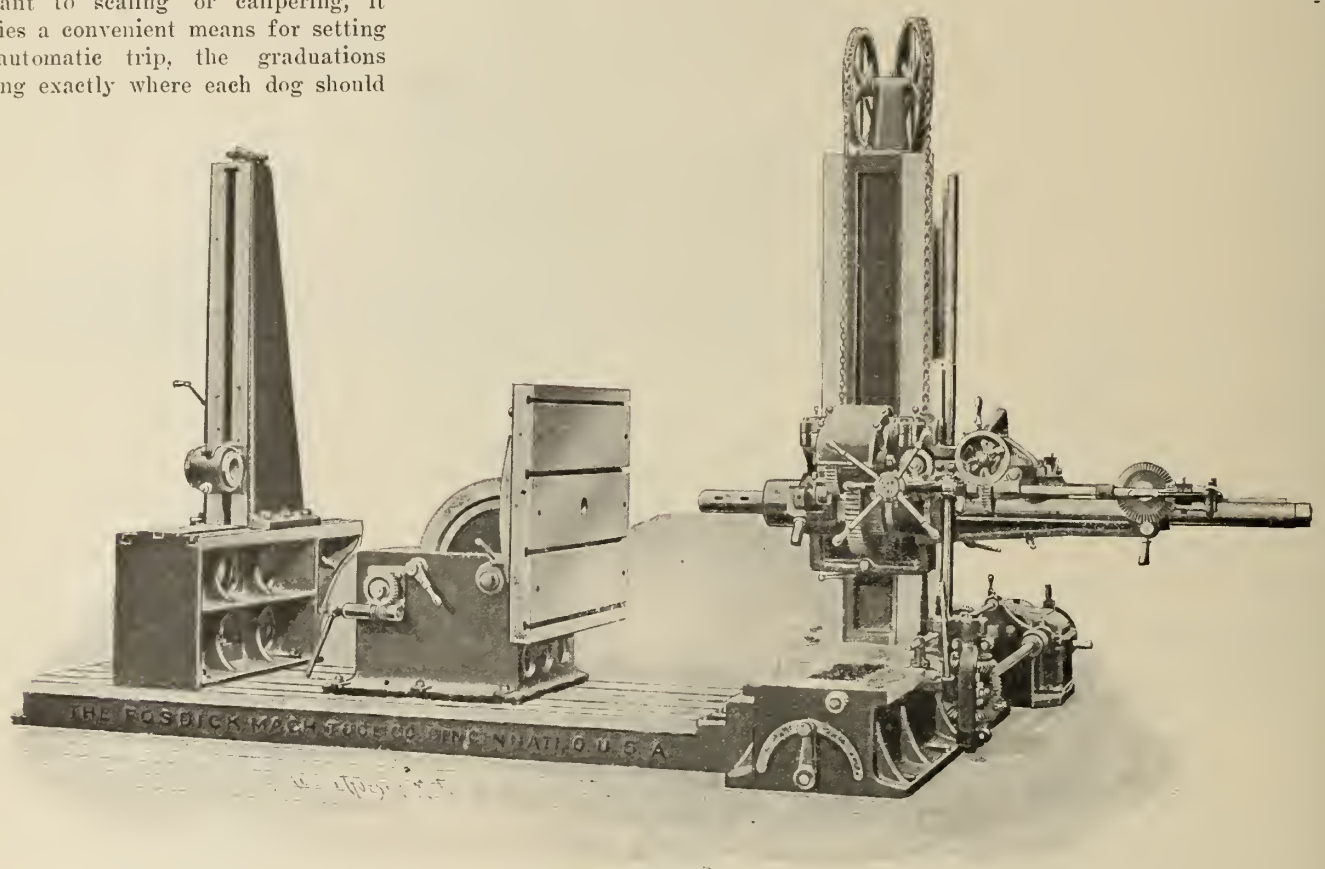
This new line of radial drills is manufactured by the Bickford Drill & Tool Company, Cincinnati, Ohio, U.S.A.

A BORING, DRILLING AND MILLING MACHINE.

The accompanying engraving illustrates a new machine, designed for boring, drilling, milling or tapping at any angle.

The machine is equipped with a constant speed drive, which can either be driven by a single belt or geared direct to a constant speed motor. A five-step cone pulley can be substituted for this constant speed drive.

The machine consists of a 42 inch x 127 inch bed plate tongued and bolted to the main bed. The wide upper surface of this bed carries the column with its saddle, which is gibbed down to a sliding fit on a wide scraped bearing.



New Fosdick Boring, Drilling and Milling Machine.

The longitudinal travel of the column on this bed is 62 inch. On this column the spindle head is mounted and is also gibbed to a sliding fit on the columns wide scraped surface. The vertical travel of the spindle head is 54 inches. The spindle head is fully counterbalanced and can be adjusted by the pilot wheel or can be raised and lowered or fed by power. Eight feeds in all directions are provided for this. The eight feeds referred to can be used as follows: To feed the column horizontally on the bed, the spindle head vertically on the column and the spindle horizontally. All these movements can be in-

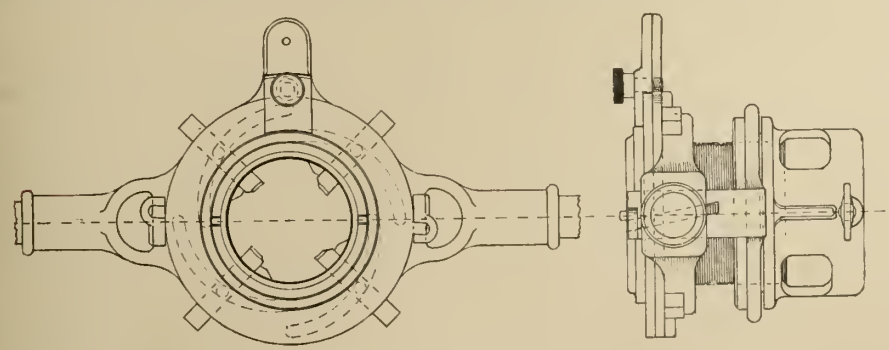
stantly reversed. The pilot wheel shown can be used to run the column forward and back, raise or lower the spindle head or run the spindle forward and back rapidly. For heavy milling, the column can be fed backward or forward on the bed. This throws the strain of the cut upon a screw of suitable diameter and lead with its ball thrust bearings. This feed can be controlled by the lever shown on semi-circular guide on the front of the machine.

The drive consists of a speed box with positive gear changes which are easily and noiselessly changed to their different speeds. This drive has six changes of speed, and with two changes on the head allows of twelve changes of spindle speed from 4 to 260 R.P.M. A friction device is placed between the back gear and the speed changing device, which can be used for starting, stopping or reversing the entire machine. The new friction is of the toggle friction type and has proven itself to be very powerful.

The spindle sleeve bearings are of very large diameter and length, and are fit into adjustable taper bronze bushings, which allow of easy adjustment for wear. The spindle sleeve is fitted with a threaded collar of large diameter, which carries a device used to securely tighten the spindle bar centrally in any position desired. The spindle bar is 4 inches in diameter, is fitted with a No. 6 Morse taper, and has 30 inches travel by hand or power.

The bed plate, which carries the universal table and outboard bearing, has a rack inserted in which the pinions (operated by ratchet wrench on the outboard bearing and universal table) mesh to operate these respective parts to and from the spindle. The outboard bearing's horizontal movement is operated by a rack and pinion, while the vertical movement is controlled by a crank and screw arrangement. Both horizontal and vertical movement of the column, spindle head, outboard bearing and also horizontal movement of the spindle are provided with scales for quick settings.

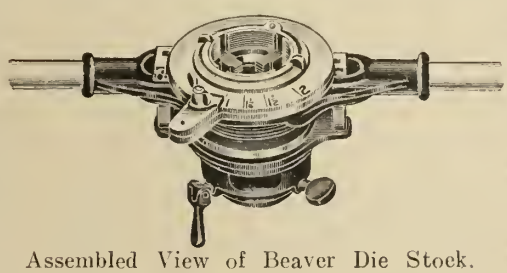
The universal table has a 40 inch x 46 inch platen, which can be tilted and swiveled to any angle. It has a hole bored through its centre to allow of passing the boring bar through to the outboard bearing. The tilting motion, as well as the swiveling motion, is imparted to the platen through a worm and worm gear in conjunction with a circular rack and pinion. The table is provided with tighteners to rigidly clamp all parts to any angle. The weight of this machine is 21,000 lbs. This machine is designed as style D, No. 2. Horizontal boring, drilling and milling machine by the Fosdick Machine Tool Co., of Cincinnati, Ohio.



Die Stock Showing Cams and Adjustable Chasers.

BEAVER DIE STOCK.

The die stock here illustrated differs from the ordinary die stock in the manner of setting the tool for different sizes of pipe. By changing the lever on the dial plate on a No. 2 Beaver stock, the chasers are set to thread four different sizes of pipe, 1 in., 1¼ inch, 1½ inch and 2 inch. A cam with four slots open up the four segments to cut the different sizes. These four segments have each three full threads, and thus the area of the cutting surface is small. The cam and dial plate are held rigidly together by means of a clamp with thumbscrew. By a simple mechanical principle they automatically recede while threading to form the tapered thread, so that they cut less depth with each turn. Small lugs on the dial plate travel in slots in the side post. These slots are 16 degrees from the perpendicular, so that the segments recede from the centre, giving a pipe-taper of ¾ inches to the foot. The first tooth of each chaser takes a roughing cut, each succeeding tooth cuts a little deeper and the last tooth makes a finishing cut forming an especially clean and perfect thread. A ring locks the side post and rear nut together. Bushings are inserted in the rear nut for different sizes of pipe. A top-locking nut holds the different parts together. Two thumbscrews and one drop-handle screw fasten the rear nut to the pipe. Chips and grit cannot work in because the tension screw collar prevents and takes up all looseness and wear. Should the pipe split the dies can be released by shifting the lever. The Beaver die stock, in six sizes, ranging from ¼-inch to 12-inch, are manufactured by the Borden-Canadian Company, 66 Richmond street, east, Toronto.



Assembled View of Beaver Die Stock.

THE DOMINION IRON & STEEL COMPANY'S OUTLOOK.

The annual meeting of the Dominion Iron & Steel Company was held in Montreal on Oct. 9. President Plummer, in his address, referring to earnings, prices and outlook, pointed out that great progress had been made in the surplus earnings. In 1905 it was $71,000, in 1906 $652,000, and it is expected that if figures keep growing through the year, the surplus earnings will show something like $2,000,000. Business is prosperous at present, and there is enough on the books and in sight to absorb all the output to the end of next season.

In regard to bounties, since the company began its operations in a finished plant in 1905, the costs have steadily decreased and have just about offset the decrease in the bounties. The president also referred to the property at Wabana, which will furnish an inexhaustible supply of good quality ore at a moderate cost.

DECIMAL EQUIVALENT AND DRILL SPEED INDICATOR.

A very handy device for machinists and foremen is here illustrated. Both sides are shown; on one side are the decimal equivalents of fractions from 1-64 inch to 1 inch inclusive, by 64ths; and the drill speed of carbon and high speed steel on the other, together with information pertaining to the feed of drills.

It is substantially made of three heavy discs of celluloid, pivotted at the centres so that they can be rotated with respect to each other. Fig. 1 gives the decimal equivalents of all the 64th parts of an inch. To determine the equivalent of any of these fractions, the smaller or upper disc is revolved until the notch in it exposes the decimal corresponding to the required frac-

tion which is shown on the outer circumference of the centre disc.

On the reverse side, as shown by Fig. 2, the outer circle of figures on the centre disc gives all the standard sizes of drills from 1 inch to 3 inch, varying by 16ths. When the smaller disc is revolved until the notch is adjacent to

Fig. 1—Decimal Equivalents.

the given size of the drill, the proper drilling speed in revolutions per minute is at once indicated for both carbon and high speed drills. This speed is adapted in drilling wrought iron, machinery steel, or soft tool steel.

Recommendations as to the feed per revolution for the various sizes of drills are given on the smaller disc as well as information to determine by observation when the maximum rate of drilling is being accomplished. Its convenient size makes it easy to be carried in the pocket and act as a ready reference. As it cannot be injured by ordinary us-

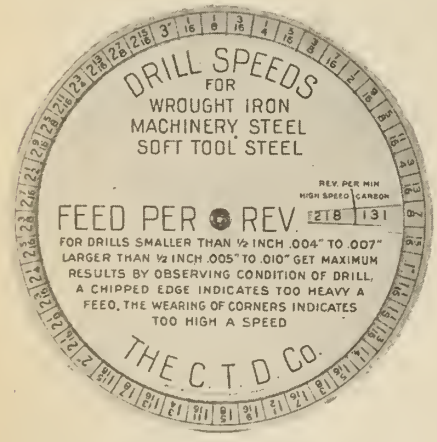


Fig. 2—Drill Speed and Feed Indicator.

age it should, therefore, last a considerable time and prove a valuable souvenir from this progressive concern. The Cleveland Twist Drill Co., Cleveland, Ohio, are distributing these gratuitously and will send them to machinists or anyone interested on application.

ABOUT CATALOGUES

By mentioning Canadian Machinery to show that you are in the trade, a copy of any of these catalogues will be sent by the firm whose address is given.

PUBLICITY ENGINEERING.—A booklet from Walter B. Snow, 170 Summer Street, Boston, Mass., on productive publicity and publicity engineering.

FINISHING GEAR BLANKS.—Sheet from Gisholt Machine Co., Madison, Wis., describing minutely, with illustrations, the operations for finishing forged steel gear blanks.

ALGOR BOILER SYRUP.—Folder from the Liverpool Borax Co., Ltd., Liverpool, explaining the use, with tests, of Algor Syrup, for stationary, locomotive and marine boilers and heating plant equipments.

OIL ENGINES.—Catalogue showing the system of working and specifications of the Blackstone Oil Engines. The Canada Foundry Company, Limited, Toronto, are the sole agents in Canada for these engines.

RIGHT ANGLE TRANSMISSION.—A folder showing the construction of the Right Angle Transmission Coupling, manufactured by the T. R. Almond Mfg. Co., 83 and 85 Washington Street, Brooklyn, N.Y.

ARC LAMPS.—A folder from the Western Electric Co., Hawthorne, Ill., giving data for their multiple alternating and multiple series direct current enclosed arc lamps. The folder illustrates a few of their types of arc lamps.

BEARING ALLOYS.—A circular issued by the Lumen Bearing Co., Buffalo, N.Y., and Toronto. It deals very fully with the various bearing alloys manufactured by this firm, and is well illustrated throughout.

STEAM SPECIALTIES.—A catalogue from Darling Bros., Limited, 2 Toronto Street, Toronto, Ontario, illustrating and describing their feedwater heaters, low and high pressure regulating valves, steam traps, pumps, oil separators and exhaust heads.

SHAPER AND AUTOMATIC TWO-SPINDLE MILLER.—A folder from the Burkes Machinery Co., of Cleveland, Ohio, describing and illustrating their Malterner hand shaper, drill presses and milling machines, with automatic rise and fall to the table.

PNEUMATIC AND HYDRAULIC RIVETERS.—A folder of the Hanna Engineering Works, 820 Elston Ave., Chicago, Ill., illustrates their full line of various styles and sizes of riveters suitable for bridges, towers, boilers, and the many works where riveters may be used.

MECHANICAL DRAFT.—Sheldon's, Limited, Galt, Ontario, Catalogue No. 22 illustrate their various blowers and engines, mill exhausters, down draft equipments for blacksmith shops and electric fans. Tables of capacities are given and a treatise on mechanical draft.

ELECTRIC MOTORS.—The B. F. Sturtevant Company, Hyde Park, Mass., have issued two bulletins, No. 144, describing eight-pole electric motors, and No. 147, describing their bi-polar and four-pole types. They describe the closed and semi-enclosed motors, and give sizes and details of each class.

OIL ENGINE.—A folder describing the new "De La Vergne" vertical oil engine, run without carburetor, spark plugs or electric ignitor. It is manufactured for both stationary and marine trade. This folder may be had by application to the De La Vergne Machine Co., foot of East 138th Street, New York City.

ARC LAMPS.—Circular No. 1084, issued by the Canadian Westinghouse Company, Limited, Hamilton, Ontario, illustrates clearly the Westinghouse Series Alternating Arc Light System, and also a pamphlet dealing with the Westinghouse Protective Apparatus for alternating and direct current circuits.

TOOLS FOR CUTTING SCREW THREADS.—J. M. Carpenter Tap & Die Co., Pawtucket, R.I. A 160-page catalogue and price list No. 17 of tools for cutting screw threads, taps, dies, screw plates, die stocks and tap wrenches. Machine nut taps, screw taps, taper taps, hobs, dies, die sets, stocks, are all described with illustrations and prices.

BRIDGE AND ROOF PAINT.—Catalogues from the Canada Paint Company, Limited, of Montreal, Toronto, and Winnipeg, describing their various paints and varnishes. A booklet on bridge and roof paint describes with colors their well-known bridge, girder and roof paints. These are intensely strong combinations of the finest weather-resisting pigments known for painting steel and iron girders, bridges and metallic shingles. Samples of their bridge paint will be furnished free on application to architects, engineers and large corporations. Their diamond graphite paints and fillers are used for finishing iron and steel castings, engines, lathes, boilers, electrical apparatus, and all kinds of machinery.

Foundry Practice

MODERN IDEAS FOR FOUNDRYMEN

Selling for the Foundry*

By Elliott A. Kebler.

While much has been written about the importance of keeping the costs of the product of the foundry, the absolute necessity of knowing the approximate cost of castings before bidding on the work has not been sufficiently dwelt upon. It is the custom of founders to glance at a pile of blue prints, and if they appear similar to work which has been done before, the price is made the same as was obtained for the other work, and too often, when it reaches the foundry, unexpected difficulties arise which add greatly to the cost.

While it is often difficult to have a careful estimate made in advance by reason of lack of time or insufficient data, if a foundryman absolutely refuses to quote until he has made an estimate, he will find in nearly every instance his customer will allow him sufficient time to make his estimate, and his profits at the end of the year will be greatly increased.

Get Correct Estimates.

To sell satisfactorily a foundryman must know that his estimates are correct, for this will give him a confidence in the price at which he is offering his castings that cannot be obtained in any other way, in fact, an estimate which is not afterward verified by the actual cost is of but little value. As an instance of this, a foundry which based its quotations on an estimate sheet, compiled by its superintendent in consultation with his foreman, adopted one on which the detailed actual cost was also entered after the work was completed, so that at a glance the correctness of each item in the estimate could be seen. When this new form was first used the estimates were found to have been very unreliable, but after the differences between the costs and estimates had been pointed out, the superintendent and his assistants soon learned to make correct estimates.

A serious mistake is made by some foundrymen who base their quotations on the prices named by others. A mill whose castings, while apparently similar to that of other plants, but were really much more expensive to make, secured its repairs for the first year at less than cost, and continued doing so by placing its orders for succeeding years with different foundries at approximately the same price by showing the bidders the figures which they had paid in preceding years. In fact unless a foundryman knows by actual experience, or can figure the costs of the castings required, it is very dangerous to take an indefinite order unless a large margin of profit is allowed. These yearly repair contracts are also unsatisfactory, for if prices of castings advance, the mill may stock up repair parts, while on a falling market, the repairs are often inconsiderable. As the profits vary on different classes of castings, a foundry salesman should keep constantly before him the desirability of securing orders which will yield the most profit, as his value to the company largely depends on this. One foundry makes a careful record of this so that a salesman who, on a smaller tonnage, obtains more returns is appreciated more than a man who fills up the shop with orders which show but little profit.

Securing Orders.

Too often foundrymen are not sufficiently alert to secure orders for work which they had not previously made, or for which castings might be used. A foundry salesman overhearing the president of a company telling his purchasing agent that some steel work which they were using was oxidizing rapidly, suggested the substitution of cast iron, and thus secured large orders from this plant and others for a class of work which heretofore had never been made in a foundry.

In fact, a decided change has taken place in the art of selling material, and to be a good foundry salesman a man must not only be a good talker, but must be thoroughly conversant with the class of castings he is selling, and often must know how they should be used to get the best results. As the buyer often relies on the representations of the seller, it is absolutely essential that the latter be honest in his statements if he wishes to hold his trade, in fact, a first order often hinges on this very consideration. Recently a buyer was in the market for some material, and clearly showed the bidders that he wished the material to have a certain peculiar characteristic. He placed his sample order not with those who flatly stated that their material would be as specified, for the buyer knew that the requirements were not fully understood, but with the salesman who frankly told him that he could not promise to fill the bill, but would sell him, subject to a sample which could be tested.

The successful salesman should also know what can be used successfully under varying conditions. He must also keep in touch with the requirements of his customers, for by so doing he may be able to convince them thgt it is to their advantage to purchase material which under ordinary conditions would be made in their own works.

* Read at the September meeting of the Pittsburg Foundrymen's Association.

MOLDER'S TOOL SUPPLIES.

By an Old Molder.

It is necessary to furnish molders with the best in the way of tools and other supplies. A molder loses much time hunting for things which should be within easy reach.

The above sentence has a variety of meanings or interpretations. The one which I wish to call attention to is the practice in different foundries of first putting new molders to work, as well as the way they have to work afterwards. What I should term well-regulated foundry practice would be to start in a new molder and show him his floor and pattern, or patterns, with some instructions as regards facing, gating, risers, etc. Then furnish him with shovel, rammer, strike-off, riddles, bellows, water sponge-pot, parting-sand pot or box, brushes, facing-bags, in fact everything necessary to do the work with, and hints thrown in in regard to the amount of work expected after a few days' experience. I forgot to mention gaggers, nails and clamps, which, in most cases have been carried off the floor. It is certainly annoying, as well as poor foundry practice, to have a new man hunting for clamps and gaggers in any foundry, most particularly a new one.

In the sense in which I am endeavoring to write in regard to Foundry Practice, the furnishing of the foregoing articles to a new, as well as the old, molder, would be called good foundry

practice, and will, I presume, be disputed by none. I am pleased to say it is the practice carried out by many foundries, but there are many where it is entirely neglected, to the detriment of the proprietors as well as annoyance and decreased output by the molder, whose time is frittered away looking for tools which should be at his hand. I have in view several large foundries which are well equipped with cupolas, electric cranes, good sand, facings and almost everything necessary to doing good work, but are sadly deficient in this one respect.

It must be the fault of someone—certainly not the proprietors, who have too much at stake. I don't see anyone to saddle it on unless it be the foreman or assistant, who have been chosen to fill the position often on account of their ability to successfully turn out large castings, and who have never done side floor work, and were accustomed to a helper handing them the tools wanted, regardless of how he got them. True, most molders, or at least quite a number, become accustomed to the way of working, and in candor I am compelled to say, like it. It's no fault of theirs and it's as easy to be looking 'round for something you can't find as it it to be ramming or shoveling sand.

I worked in a large steel works which has since become extinct, in my opinion due to this kind of foundry practice as much as other causes and probably more. I think they had over a half-million dollars invested in buildings, furnaces, electric cranes, etc.; worked a large number of molders and ran day and night gangs. When you went in in the morning the assistant foreman gave you a pattern. You had to hunt up a flask, temper up the sand (if there was any to temper). Then began a hunt for waterbuckets, of which there were only a few, and they were to be found in all kinds of improbable places, and so you went hunting for everything the whole day long. You picked up a rammer or shovel or riddle and laid it down. The next time you wanted it someone was using it. So it was with brushes, bellows. Everything belonged to everybody. While the foreman stood looking on or rushing around seeing nothing and caring nothing for the waste of time, which is great where a molder is working on side floor on smaller work.

Some folks might think this a fancy sketch of foundry practice, especially some of the proprietors, who never look into such small matters. I called a foreman's attention to it once and he told me he had to keep down foundry expenses to hold his position.

F. B. Polson, president of Polson Iron Works, Toronto, died suddenly on the afternoon of October 28th.

OCTOBER METAL MARKETS.

Pig iron throughout the past month and, in fact, throughout the past two or three months, has maintained a splendid activity. Not even stringent financial conditions have been sufficiently serious to affect the demand for it. Canadian consumers have come into the field and have bought very liberally considering the existing circumstances. The steadiness of the British market since the middle of the year is a matter of surprise, especially when it became plainly apparent that the end of demand from the United States was imminent. Quotations on Scotch and English iron have been very firm, owing solely to the strong demand. Statistics published by a prominent Glasgow firm show that on September 19 of this year only 166,951 tons of Scotch iron were available, as against 582,272 tons on September 20, 1906.

Antimony has gradually become a little firmer. Very little business has been transacted. The market does not yet perfectly satisfy the consumers and, although American prices have slightly advanced, dealers show a willingness to make concessions to stimulate heavy buying.

Copper has been affected more seriously by recent developments in the money market than any other metal, perhaps, as it is more subjected to speculative fluctuations. Throughout the past month quotations have been very weak and transactions have been limited to small volume. The majority of the American producers have adopted the curtailment of production policy with the result that the output has been reduced on the basis of 25,000,000 pounds per month. Although prices have been actually cut in two in the past six months, dealers console themselves by thinking that the prices cannot very easily be further reduced.

Ingot tin has been subject to wide fluctuations in the past five weeks, the general tendency being downward. In the first week of October there was a decline of £8, in the second week £10, and in the third week £10. Local prices have been very weak and a limited volume of business has been transacted.

FOUNDRY ECONOMY.

We are told of a recent case where a bright young engineer approached the manager of a certain foundry and offered to secure work for them on a percentage basis, at the same time to look after their buying and such other deals where he could assist them. The contract was closed and the engineer promptly got busy and filled the foundry with orders. He also installed a system of controlling the mixtures by analysis and insisted that every shipment of pig iron and coke should be analyzed. By taking advantage of the pig iron market he succeeded in saving the company a large sum of money on material.

The old management, however, did not see this, but looked mainly at the figures representing 5 per cent. of the gross selling price of the castings, which would go to the engineer each month. For several months they simply complained and then began to look around for some method to get rid of this expensive engineer. The contract was finally canceled and the foundry left to carry on its work as it saw fit. The plant was full of work and everything went smoothly for a short time, but among other things they just cut out that costly chemical analysis, then they forgot that they lacked the services of the engineer who used to interpret the analysis and apply the results for them.

Some of the castings were expected to fill difficult specifications and it was not long before complaints began pouring in at a goodly rate. Then work was withdrawn and withdrawn so that it could never be regained. In place of operating on high-class work in which there was a good margin, the foundry had to drop back into its old rut of standard, cheap jobbing castings. In the meanwhile the engineer found other foundry connections and started to build up a good business once more.

All of which goes to show that you get out of a foundry something akin to what is put into it.—Castings.

CUPOLA PRACTICE.

By T. U. Burman.

Having erected and had the care of thirteen different cupolas for melting soft grey iron in different parts of the country, I have found that the cupola furnace is about the same as a pot with air forced into it, only some require a high set of tuyeres and some a low set, some require a low pressure of blast and some high. I have learned that all other parts of the practice being equal, I can get more good results out of the coke and iron of the kind made these days, though both coke and iron have more impurities in them than they did 25 years ago. All foundrymen are having some trouble with the coke and iron, so if I can tell any brother foundryman anything to aid him, I want to do so. In our plant we make light castings to stand a water pressure of 80 pounds, and some to stand 180 pounds. We use a southern coke, fairly good hard coke, but all the cars are not the same, some come in with coke

softer and lighter with more sulphur, and some come in a bright heavy coke with less sulphur, all from the same company and region. Having been among the coke ovens and men who work at them for two years, I know how the unevenness in coke comes. The good or best coke has been burned more hours. I had a car come into the yard near Pittsburg, and I said to a laborer I had, who one time worked coke ovens: "That looks good, it must be 72-hour coke." "No, sir," he said, "I drew many an oven at 36 hours burning." I find that the heavy and bright with very little black coal on the large pieces proves the burning of it. Now I hope no good brother will let happen what did to me. We had plenty of coke, and our iron was full of scruff and sulphur. My melter had a heavy heat of 26 tons in a 42-inch cupola all hot iron. Our man, Jack, the coke man, got hold of all large pieces, and, as it happened, the big pieces were very much topped with coal not burned well. It seemed almost impossible that heat to keep hot iron and the loss ran away up. We discovered this on the next heat, and had fine iron and have had ever since. Our coke man does not get all the coke from the same pile now. We have him get his loads from three piles, so he cannot get all black-heads. We use a flux and the flux brings out with the slag a yellow, bright, spongy mass, almost all sulphur. Before we used the flux, we did not get that, and sulphur went with our iron into our radiator and they were spongy. I find the larger coke in the first seven charges in the cupola will gain speed, and the small coke in the last nineteen charges would melt as fast and at the very last faster. The large coke about the tuyeres and slag hole is a great help to get slag to run free, and easy to manage. All these things have been gained by years of hard work, and now anyone can get it by reading. I want to answer a question I saw in the Foundry some weeks ago. Someone wanted to know why a cupola boiled slag over into the tuyeres. When a cupola is properly arranged with tuyeres and slag hole, and the slag allowed to flow out it will not go into the tuyeres. If one day or many days the cupola is not run dry and the bottom is dropped with some pig and coke in it, as it should be, and on some other heat the blast is kept on a long time after the iron is all melted out, the slag and sulphur on the walls of the cupola will melt and run down like molasses and go into all the places it can get in. So be careful and not melt out your brick work as it costs money.

COST OF A SMALL STEEL FURNACE.

The increasing inroads which cast-steel is making in the business of the manufacture of light gray iron castings have caused some founders to install a small steel furnace running 5 or 6 tons per day, and they have found, in the main, that it was a profitable investment.

A 5-ton furnace, basic lined, erected in an active iron foundry, would cost about $6,000, and allowing $4,000 for special bottom, pouring ladles, oil storage tanks, burners, etc., the total would be $10,000, exclusive of buildings. It would be capable of producing three heats daily and would yield 12¾ tons of castings at the rate of 15 per cent. in melting loss, gates heads, skulls and defective castings, an average yield in a well ordered plant. Producing such tonnage steadily should show good profits. The single furnace, however, has the disadvantage of going out of commission for repairs. It should turn out 400 heats before a general overhauling, or say a run of 133 working days. Assuming that the furnace was only productive nine months of a year at 25 working days per month, there would then be 225 days yielding a total output of 2,868¾ tons of product. Allowing an average profit of one-half cent per pound, there would be a gross profit of $28,687.50 annually.

But losses will arise in spite of best intention and not to make the venture look too roseate the setbacks will be considered which might be caused by breakdowns, strikes, or errors on practice. These conditions might reduce the good castings to one-half of the metal charged, so that 7½ tons were the output. With the same productive period of 225 days per year, and with a decided shrinkage, because of losses, between manufacturing costs and selling prices so that the gross profit was only one-eighth cent per pound, the tonnage per year would be 1,687½ tons, and the returns therefrom $4,218.75. Out of this, 25 per cent. can be deducted for interest on the investment, depreciation, etc., there would remain a net profit of $3,164.07, which is equivalent to 31.6 per cent. on the original $10,000.—Popular Mechanics.

BOOK REVIEWS.

A COURSE OF STRUCTURAL DRAFTING.—Compiled and arranged by W. D. Browning, M.E., Collingwood, Ohio, describing material used in structural design and drafting room practice, relating to it, with fifteen plates for students ; price $1 net. Published by the Industrial Magazine, Collingwood, Ohio.

This is the first treatise of its kind and it is fully illustrated throughout to make all points clear. Tables are inserted giving sizes of standard I-beams, angles, channels, etc., rivets are taken up in detail and signs relating to same; also the design of bolts, eyebars and pins, turnbuckles, anchors ; the strength of different materials, beams, girders, columns, trusses, drawing-room practice and plate lettering.

As it is a good thing for every mechanic to be able to understand drawings, and sometimes to make a drawing, this work is of considerable value to one wishing to make a study of drafting.

5,000 FACTS ABOUT CANADA.—A 70-page booklet, compiled by Frank Yeigh, Toronto, and published by the Canadian Facts Publishing Co., of that city. It has chapters dealing with every subject of national interest and industrial and commercial progress. Some of the following chapters will be of special interest to our readers :—Mining, Milling, Manufacturies, Railways, Trade and Tariff, Water Powers. Official figures are given where interesting, thus making it a valuable book to industrial men.

OPEN-HEARTH STEEL CASTINGS.—An exposition of the methods involved in the manufacture of open-hearth steel castings by the basic and acid processes, by W. M. Carr ; 118 pages, 5x7½ inches ; illustrated, cloth; published by the Penton Publishing Co., Cleveland, Ohio.

This book is compiled from a series of articles by the author appearing in the Foundry and the Iron Trade Review. The author being an authority on this subject, the information is very reliable.

HOW TO USE WATER POWER.—By Herbert Chatley, B.Sc.; fully illustrated ; 87 pages, Technical Pub. Co., Manchester, Eng., and by D. Van Nostrand Co., New York ; price, 2s 6d.

This is a short and clear account of the methods and principles of hydraulic engineering, produced in a form that can be easily grasped by those with limited knowledge of mechanics and hydraulics. The illustrations are clear and to the point.

THE 20TH CENTURY TOOLSMITH AND STEELWORKER.—A complete treatment of the manufacture of steel into tools, written in the interests of blacksmiths, toolmakers, etc.; by H. Holford ; 240 pages, 5x7½ inches ; fully illustrated ; cloth ; published by Frederick J. Drake & Co., Chicago.

This book is written by a man who has had practical experience in many shops, and is written in a simple style. The illustrations are simple and easily understood.

Industrial Progress

CANADIAN MACHINERY will be pleased to receive, as confidential, industrial news of any description, the incorporation of companies, establishment or enlargement of plants, railway, mining or municipal news.

New Plants and Additions.

A heavy flow of naturnl gas has been struck nenr Calgary, Alta.

The Cnnada Boiler & Rndiator Co., Hastings, Ont., hns assigned.

McDonnld, Man., is to have a new eourt house, costing $40,000.

The Livingstone flax mill at Brussels, Ont., was destroyed by fire.

The Chatham Gas Co., Chatham, Ont., have completed their plant.

Windsor Hotel, Winnipeg, is to be enlarged, at a cost of about $25,000.

The J. Y. Griffin Co. are planning to erect a $100,000 warehouse and office.

A new fire hall, costing $25,000, is being erected at St. Bonifacc, Man.

The Brandon Brewing Co.'s new warehouse, at Brandon, Man., will cost $25,000.

The Standard Valve & Fitting Co., Guelph, Ont., will soon enlarge their works.

The Brunswick-Balke-Collender Co. will ereet a factory in Toronto, to cost $30,000.

A Detroit firm, manufacturing malleable iron, wishes to loeate in Parry Sound, Ont.

An electric plant will be installed at Torbrook Mines, N.S., at a cost of $40,000.

The planing mill of Wm. Drader, Chatham, Ont., was destroyed by fire; loss, $50,000.

A large sawmill, with a daily capacity of 45,000 feet, will be erected at Nelson, B.C.

The Lake Huron Lumber Co., Ottawa, have assigned, with liabilities amounting to $45,000.

The Delaware Seamless Tube Co., Auburn, Pa., will erect a plant at Sarnia, Ont., to cost $200,000.

The bridges and locks on the Welland canal will be operated by electric motors next season.

The Canadian Portland Cement Co., Welland, Ont., are installing four rotary kilns, 150 feet long.

Plans have been prepared for a $6,000 machine shop for Matthew McNaughton, Calgary, Alta.

Valuable deposits of radium have been found in the Simplon tunnel, between Switzerland and Italy.

The Lloyd, Thompson Wire Co., Toronto, have gone into liquidation, with liabilities of about $33,000.

The newly organized Dominion Tool Company, Peterboro, have purchased a site for their new factory.

David Spencer, Limited, Vancouver, is erecting an eight-storey warehouse, at a cost of $120,000.

The Prince Albert Lumber Co., Prince Albert, Sask., suffered loss by fire to the extent of $10,0000.

A system of marine telephones has been installed between seven stations on the St. Lawrence.

The works of the Standard Drain and Pipe Co., New Glasgow, N.S., will be rebuilt immediately.

Geo. White & Sons, London, Ont., are considering the removal of their plant to St. Catharines.

An American syndicate has proposed to establish a large cement works on the St. John river, N.B.

The affairs of the Truro Foundry & Machine Co., Truro, N.S., will be wound up and the plant sold.

The British Columbia Bedding & Upholstering Co., Vancouver, B.C., suffered heavy damage by fire recently.

The capital stock of the McLaughlin Carriage Co., Oshawa, has been increased from $400,000 to $1,500,000.

The new factory being erected at Hull, Que., by J. W. Woods is nearing completion. It will cost $100,000.

Zuelsdorf Bros., Berlin, Ont., will erect a factory in that city ior the manufacture of high-grade furniture.

C.N.R. bave awarded the contract for a new roundhouse at Brandon, Man., to the Sharp Construction Co.

J. E. Doak, Saskatoon, Alta., will erect a factory for the manufacture of all kinds of house furnishings.

The Orangeville Woolen Mills, Orangeville, Ontario, were destroyed by fire recently, entailing a loss of $12,000.

A new invention makes it possible to reverse steam turbines. This will be appreciated in shipbuilding circles.

The Peterboro Lock Co. will, it is expected, erect a factory addition to their present premises, Peterboro, Ont.

J. E. Doak, Doaktown, N.B., will erect a factory in Saskatoon, Sask., for the manufacture of house furnishings.

A company manufacturing furniture will locate in New Hamburg, Ont. A loan has been granted by the town.

A firm manufacturing engines is considering the erection of a plant at Leamington, Ont., to cost about $38,000.

A firm manufacturing engines wishes to loeate in London, Ont. They want $25,000 or $30,000 as an inducement.

A company formed chiefly of Chinamen, and called the Sydney Brick & Tile Co., will erect works at Sydney, B.C.

The new factory of the King Radiator Co., Toronto, is nearing completion. The whole plant will cost $250,000.

Clark Brothers have opened up a machine shop at 164 Duke street, for the manufacture of their friction clutches.

The new post office building at Edmonton, Alta., will be fireproof throughout. It will be in use early in the spring.

Plans have been completed for a eorrugated iron warehouse for the Paris Plow Co., Paris, Ont., to cost about $9,000.

Canadian Condensed Milk Company, Limited, Hamilton, have a large plant in course of erection at Alymer, Ontario.

It has been announced that MacKenzie & Mann will double the capacity of their blast furnaces at Port Arthur, Ont.

George Brown, of San Francisco, Cal., will at once commence the erection of a large lumber mill at Prince Rupert, B.C.

The grist and planing mills of T. A. Vaughan, St. Martin's, N.B., were destroyed by fire recently, entailing a loss of $5,000.

The International Harvester Co., of Hamilton, are contemplating the erection of a distributing warehouse at Port Arthur, Ont.

P. Venables, R. G. Venables and another local party are preparing to build a large cold storage plant in New Westminster, B.C.

Shipments of machinery have been arriving lately for the Sarnia Brass Works. The company will manufacture plumbers' supplies.

An American company, manufacturing farm implements, garden swings, ladders, etc., is looking for a site for a Canadian factory.

The Fawcett Manufacturing Company's foundry, at Saskville, N.B., was damaged to the extent of $3,000, by fire. There is no insurance.

F. W. Birks & Son, makers of Paroid roofing and waterproofs, are looking for available sites for manufacturing goods for the Canadian market.

Walker & Sons, Walkerville, Ont., will erect an addition to their planing mill. Additions will be made to the boiler and engine equipment.

A ferro-nickel smelter is now under construction at Sault Ste. Marie. White metal for cutlery will be manufactured by the ferro-nickel process.

The Interwest Peat Fuel Company's plant, Lac du Bonnet, Man., was destroyed by fire last week. Loss, $40,000, partly covered by insurance.

Defective electric wiring is supposed to have been the cause of a fire that destroyed the building and plant of Parker's laundry works, Peterboro.

The power plant of the Maine & New Brunswick Electrical Power Company was opened recently. The plant is situated at Aroostook, Falls, N.B.

The Grand Bay lumber mill, St. John, N.B., was destroyed by fire on Monday. The loss of $15,000 was covered by insurance to the amount of $11,000.

The Automatic Telephone Co. is considering the erection of a factory at Guelph, Brantford or Welland. The factory at Toronto is not large enough.

The Sherwin-Williams Paint Co., Montreal, took out a permit for the erection of a new three-storey warehouse on St. Patrick street, to cost $20,000.

Messrs. Shurly & Dietrich, Galt, Ont., will erect a sheet metal building 163 feet long, equipped with every modern device for the tempering of saws.

The new plant of the Berlin Manufacturing Company, of Hamilton, is nearing completion. They will manufacture a full line of woodworking machinery.

The Standard Contracting Co., Toronto, have bought a building in that city and will install a plant to cost $30,000 for the manufacture of machinery and tools.

J. J. Murray & Co., Cayuga, Ont., will erect a gas pumping station and reservoir for the Dominion Gas Co., near Canfield, Ont. The contract price is $35,000.

The Tacoma Construction Co. are asking New Westminster, B.C., for a free site on Lytton Square, in order to erect a hotel and business block, at a cost of $200,000.

The Industrial Development Company, of Canada, manufacturers of tar, turpentine, alcohol, etc., have been offered ten years' exemption from taxation by Hull, Que., council.

The Evans Rotary Engine Co. Toronto, has the contract to install one of their 40 horsepower rotary engines for the lighting and heating of the Rossin House, Toronto.

M. L. Aubert, Montreal, a member of a firm of French capitalists, is negotiating with Hull, Que., for the erection of a large biscuit and confectionery factory in that city.

The Colonial Engineering Co., Montreal, have the contract to install a 75 horse-power Hornsby Stockport gas engine in the plant of the Queen City Printing Ink Co., Toronto.

The Windsor Foundry, Windsor, N.S., which was put up for auction recently, was purchased by Geo. Mounce, of Avondale, for $18,000. The foundry will commence work immediately.

Mr. Chapman, head of the Ontario Wind, Engine & Pump Co., Toronto, and Mr. Fleury, of J. Fleury & Sons, Aurora, Ont., have taken over the Bell Foundry, St. George, Ont.

The American Electrical Furnace Co. will erect a Canadian factory at Niagara Falls, Ont. They will manufacture iron and steel castings, the melting being done by electricity.

The Porto Rico Co., Nelson, B.C., will erect a lumber mill, with a daily capacity of 45,000 feet. The limits possessed by the company are conservatively estimated at one hundred million feet.

The Southern Cross Mining & Smelting Co., Victoria, B.C., propose to have erected before next spring a smelter to cost at least $500,000. H. Cecil, of that city, has the matter in hand.

Mayor Lyle, of Smith's Falls, has replaced his saw-mill, which was destroyed by fire a few months ago, with a large, new fire-proof mill. New, up-to-date machinery will be installed.

The Albert Sawmills, Baraehois, Que., were recently totally destroyed by fire, together with the wharf and all the buildings connected with the mills. Five million feet of lumber also disappeared.

An English company is said to be behind the locomotive works to be erected at Lachine, Que. The works will cost $3,000,000. The company wants a bonus of $50,000 and exemption from taxation.

A. C. Flumerfelt and H. N. Galer have acquired a large area of rich coal deposits near Lethbridge, Alta. A company has been formed to develop the deposits and a large plant will be installed at once.

The Fleming Aerial Ladder Co. have submitted a proposition to the town of Barrie, Ont., for the erection of a large plant there to cost $26,000. They want a loan of $20,000, and a fixed assessment of $5,000.

I. S. G. VanWart, president Albert Biscuit Co., of Calgary, and the manager, E. B. Johnson, are considering the establishment of a branch factory in Edmonton, Alta., at an estimated cost of $150,000.

A company with a capital of $50,000 proposes to erect a factory for the manufacture of cement bricks at New Westminster, B.C., providing suitable deposits of sand and clay can be found in the vicinity.

The Canadian Marble & Granite Works have recently been opened in Edmonton, Alta. The machinery for cutting and polishing the marble has been installed. Stone of the best quality is quarried near Nelson, B.C.

The Berlin Machine Works, of Beloit, Wis., has installed a Newton patent cupola, having a capacity of sixteen tons per hour. A cupola of the same make will be installed in their Canadian plant at Hamilton.

The Fairchild Co., Winnipeg, will sell all interests to the John Deere Plow Co., Moline, Ill., under a Dominion charter, with a capitalization of $1,000,000. It is to be known as the John Deere Plow Co. of Canada.

Large shipments of machinery have recently been arriving for the plant of the Central Foundry Co., Port Hope, Ont. Over $100,000 has been spent already and the plant will be ready for work in a short time.

Architect Chas. Mills, of Hamilton, Ont., has awarded the contract for the erection of a large addition to the Eagle Spinning Co.'s works there, to the Provincial Construction Co., of Toronto, at a cost of $50,000.

The strike at the Springhill, N.S., Coal Mines has now been on for two months, and the Government of Nova Scotia will on Wednesday take charge of the work heretofore done by members of the Mechanics' Lodge of the Collieries.

The Thames River Oil and Gas Company wants a franchise from the town of Aylmer, Ont., for power to enable them to pipe the town for purposes of supplying natural gas for power, heating and manufacturing purposes.

The new exchange building for the automatic telephone system now being installed in Edmonton is almost completed, the machinery being installed. The Mortimer automatic system is being used. It will be ready by November.

B. Ledoux & Co., Osborne street, Montreal, have been granted a building permit for the erection of an addition to their carriage factory. The structure will be [illegible] with a frontage of 75 feet, and about 90 feet deep.

The Industrial Financial Co., Toronto, propose establishing a piling and engineering works at Kincardine, Ont. The company wants a loan of $50,000 and will manufacture the Hunter Patent Interlocking Pile, having the rights for Canada.

Traces of graphite in Haliburton county, Ontario, are being investigated by Eugene McSweeney, president of the United States Graphite Co., Saginaw, Mich. It is said the deposits are rich along the line of the I. B. & O. Railway.

The Shortells, Limited, Wood Alcohol and Charcoal Company are considering the erection of a plant at Parry Sound, Ont. The plant will cost $50,000, and 500 hands will be employed at first. They want a loan of $30,000, which the town has endorsed.

Three industries are looking for a location in Berlin. They will manufacture collapsible go-carts, concrete machinery and washing machines. The outlay will be $100,000, and 300 hands would be employed. Certain conditions will have to be fulfilled.

The organization of a company for the manufacture of railway cars in the Canadian west is being effected in Toronto. Winnipeg is being considered as a location for the factory. The company will have a capital of $2,000,000, and will employ 1,000 hands.

The Georgian Bay Power Co. are developing power at Eugenia Falls, near Flesherton, Ont. They propose building a large dam about 40 rods above the falls and piping the river through a large hill to the Beaver valley. About 3,000 h.p. will be developed at first.

For the first eight months of this year the total immigration to Canada was 216,865, an increase of 50,058 as compared with the first eight months of 1906. The total for the eight months is more than the total immigration during the whole six years, 1896 to 1902.

Canadian Rand Co., Limited, of Montreal, have opened up a show-room at 11 St. Nicholas street, where they display a complete line of air-compressors, rock drills and Imperial pneumatic tools. A stock of repair parts will also be carried for the convenience of local customers.

The Dominion Heat & Vent Co., of Hespeler, have closed contracts for the heating and ventilating of the Parkin elevator works, of Hespeler. They have also supplied a Toronto firm with one 160-inch double discharge steam fan, and 8,000-foot heater, and also one 120-inch fan and 4,800-foot heater.

The Canadian Rubber Company, of Montreal, has been appointed sole agents in Canada for "Rainbow" red sheet packing and "Eclipse" gaskets, manufactured by the Peerless Rubber Manufacturing Co., New York. Orders for these goods may be sent direct to any of the company's sales branches.

The International Heating and Lighting Co., Edmonton, Alta., will erect a plant for the manufacture of producer gas from straw. The plant will cost $100,000, and mains will be laid to pipe the gas to all parts of the city. Over thirty miles of these mains will be laid, entailing an expenditure of $200,000.

The Canadian Steel Specialty Co., of Gravenhurst, Ont., will erect a two-storey factory in that town, together with a boiler house and dry kiln, at a cost of $10,000. The company will manufacture steel furniture, electric fixtures, and novelties. The town has granted a free site and exemption from taxation.

The Edmonton Produce Co., Edmonton, Alta., proposes to erect a cold storage building and install therein a refrigerator plant, the whole to cost not less than $50,000, if the by-law voted on by the taxpayers of that place passes. If arrangements are satisfactory, building operations will be commenced not later than January, 1908.

The Hanover Portland Cement Company is enlarging its plant, the following contracts having been placed: Canada Foundry Company, for two 250 horse-power boilers, condensers and pumps; Kilmer & Pullen, Toronto, for one 400 kilowatt generator; the Robb Engineering Co., Amherst, N.S., for one 500 horse-power engine.

The new plant of the Standard Chain Company, of Canada, now being erected at Sarnia, is progressing very rapidly. The dock has been entirely completed and the main building will shortly be under roof. The blast system is being furnished by Sheldons, Limited, of Galt, Ont. It is anticipated that the plant will be in operation the latter part of October.

The new machinery at the Canadian Locomotive Works, Kingston, Ont., is nearly all installed and the buildings are fast nearing completion. The new power house is practically completed and ready to have the steam turned on. The new switch board being installed by the Canadian Westinghouse Company, is in place, and is one of the best ever installed in that city.

The Dominion Bridge Company, of Lachine, of which James Ross is president, will increase its capital from $1,000,000 to $1,500,000. This course has been found necessary by the great expansion of business and the large additions to the company's several plants. New shops are being built in Toronto and Winnipeg, and very extensive additions to the plant at Lachine are likewise being undertaken.

It is announced from Owen Sound that the Northern Navigation Company are inviting tenders for a new passenger and freight vessel 259 feet in length, to take the place of the wrecked Monarch. Plans and specifications have been prepared by Hugh Calderwood, marine architect. It is intended that the steamer will be ready to go into commission on the opening of navigation next spring.

London Fence, Ltd., Portage la Prairie, have decided to rebuild their factory, which was destroyed by fire early in the year. For some time there was uncertainty as to the future plans of the company, owing to the dispute with the insurance companies as to the amount of the fire losses. However, the fire losses have been adjusted, and at a meeting of the shareholders, held last week, it was unanimously decided to rebuild.

The Dominion Wrought Iron Wheel Works, Orillia, is enlarging its factory premises by the addition of a 40x50 brick building with metal roof to be used as a foundry, and a 40x20

metal-clad storehouse. The new buildings are west of the present factory, and close to the railway switch, which will be convenient for handling supplies as well as shipping the finished products. The Wheel Works is one of Orillia's rapidly expanding industries.

It has been discovered that the new C.P.R. Assiniboia, which has been cut in two at the graving dock at Levis, Que., for the purpose of taking her through the canals to do service on the lakes, would not float. Her ballast will, therefore, have to be shifted, and this operation was begun this morning. As soon as this vessel leaves port her sister ship, the Keewatin, will undergo the same operation of being severed in two, and also leave to do service on the lakes.

The Peel Oil and Gas Co. has let contracts for the sinking of oil wells on the property of the company at Cooksville, 16 miles west of Toronto. This organization has over 1,000 acres of land under option, and it is expected that deposits of oil or natural gas will be encountered. Some years ago natural gas was obtained in a shaft sunk a few miles west of Mimico, but, owing to a lack of facilities for handling the product, the well was plugged. The above company expects that if the venture proves successful it will be able to supply natural gas at a cheap rate to Toronto.

The Smart-Turner Machine Company, Limited, 191 Barton street, east, Hamilton, Ont., report a brisk demand for their steam pumps. Among the firms who have been supplied are ; E. Leonard & Sons, London ; Johnston Bros., Jarvis; Canada Paint Co., Toronto ; Fred. Armstrong, Toronto ; McColl Bros. & Co., Toronto ; Hiram Walker & Sons, Walkerville ; the John Whitfield Co., Toronto ; the Biggs Fruit and Produce Co., Limited, Burlington ; J. W. Holmes, Selkirk ; H. B. Kinster & Co., Woodslee, and E. Van Allan & Co., Hamilton.' These pumps include the Smart-Turner duplex, automatic feed and side suction centrifugal pumps, with accessories.

The National Light & Manufacturing Co., of London, Ont., have applied for incorporation, with a capital of $50,000. The company have acquired the patent rights for Canada of the Cody inverted gas lights, and inverted arc lights, and the Keller gas governing devices, and have also become owners of the Cody oil gas patents, including the only known method of generating a non-carbonizing gas from common coal oil. The latter, on account of its absolute safety, freedom from odor, and lower cost, is calculated to entirely replace gasoline and wick-using lamps for both lighting and cooking, and the firm will handle a full line of stoves and arc lights constructed on this principle. The premises, leased for six years, cover some 10,000 feet of floor space, and a staff of about 25 men will be employed as soon as the work of equipment is completed. The firm is already shipping out gas lights and will be accepting orders for the oil-gas lights and stoves in a few days.

Companies Incorporated.

The Joliette Light, Heat and Power Company, Limited, has been incorporated.

Monarch Electric Co., Montreal ; capital, $20,000 ; to manufacture electrical machinery. Incorporators, J. R. Lewis, J. W. Schlieffers and H. S. Poole, all of Montreal.

The Nanton Coal Fields, Limited, Ottawa ; capital, $100,000. To prospect, reduce ores, etc. Provisional directors : A. B. West, A, N, McLean and J. A. Rawley, of Ottawa.

Shurly & Derrett, Toronto ; capital, $75,000 ; to manufacture and deal in twine, hemp, flax, etc. Provisional directors, C. J. Shurly, T. F. Shurly, Galt, Ont.; G. D. McAllister, Toronto.

Cobalt Silver Fountain Mines, Toronto ; capital, $500,000 ; to carry on mining, milling and reducing ores. Provisional directors : P. S. Hairston, J. H. Stephens and R. McKay, Toronto.

The Chatham Carriage Co., Chatham, Ont.; capital, $100,000 ; to manufacture all kinds of vehicles. Provisional directors, Ira Teeter, Arthur Cooke, Frank E. Fisher, all of Chatham, Ont.

Wilbur Iron Ore Company, Toronto ; capital, $500,000 ; to prospect for and deal in ores, metals and minerals. Incorporators, C. L. Dunbar, E. A. Dunbar, and H. C. Scholfield, all of Guelph, Ont.

Ahern Safe Co., Montreal ; capital, $75,000 ; to manufacture and deal in locks, keys, safes, vaults and hardware pertaining to same. Incorporators, R. M. Ahern, A. Ahern and A. D. Ahern, all of Montreal.

The Lovering Lumber Co., Toronto, have been incorporated, with a capital of $100,000, to manufacture lumber, timber, etc. The provisional directors include, J. F. Hollis, T. H. Wilson and W. J. Lovering, Toronto.

The P. Hymmen Company, Berlin, Ont.; capital, $60,000 ; to take over the hardware and plumbing business of Peter Hymmen, Berlin. Provisional directors, P. Hymmen, H. Hymmen and H. S. Hymmen, all of Berlin.

The Producers' Natural Gas Co., Hamilton, Ont., have been incorporated with a capital of $100,000, to manufacture oil, gas, ores, etc. The provisional directors include, W. Southam, J. Milne and F. A. Magee, Hamilton.

Wm. G. Hartranft Cement Co., Montreal ; capital, $25,000 ; to manufacture and deal in Portland cement, gypsum, etc. Incorporators, G. W. MacDougall, L. Macfarlane, C. A. Pope, and A. Swindlehurst, all of Montreal.

The Right-Process Co., Toronto, have been incorporated with a capacity of $40,000, to manufacture washing compounds, etc. The provisional directors include A. H. Brother, W. McLean and W. C. Ormsby, Barrie, Ont.

The Canadian Thermos Bottle Co., Montreal, have been incorporated, with a capital of $300,000, to manufacture bottles, glass, metals, etc. The charter members include, L. Macfarlane, J. B. Schwabacher and C, A. Pope, Montreal.

Queen City Foundry Co., Toronto ; capital, $40,000 ; to manufacture and sell boilers, hardware, ranges, locks, etc. Provisional directors, E. Gillespie, W. C. Burt, J. W. Clark, J. Brooks and R. J. Smythe, all of Toronto.

The Spears Mining Corporation, Toronto, have been incorporated, with a capital of $50,000, to carry on a mining, milling and reduction business. The provisional directors include, D. A. Rose, F. W. Rose and R. S. Gilpin, Toronto.

Dunelin, Limited, Hamilton, Ont., have been incorporated, with a capital of $100,000, to carry on a navigation and transportation business. The provisional directors include, R. O. MacKay, J. P. Steedman and G. Somerville, Hamilton.

The Toronto Yarn Spinning Co., Toronto, have been incorporated, with a capital of $100,000, to manufacture woolen, worsted, cotton yarns, etc. The provisional directors include, J. A. Murray, J. P. Murray and F. B. Hayes, Toronto.

Dominion Crown Cork Co., Toronto ; capital, $15,000 ; to manufacture and deal in crown corks, wire, tin and other metals, metal stamping and cork. Provisional directors, W. F. Hayes, Gordon Russel, Violet Waldock, all of Toronto.

The Canadian Smelting & Refining Co., Toronto, have been incorporated, with a capital of $2,500,000, to carry on a smelting and refining business. The provisional directors include, W. M. Wallace, A. G. Robertson and J. D. Pringle, Toronto.

The Chatham Carriage Co., Chatham, Ont., have been incorporated, with a capital of $100,000, to manufacture carriages, trucks, wagons, sleighs, automobiles, etc. The provisional directors include, I. Teeter, A. Cooke and F. E. Fisher, Chatham.

The Standard Contracting Co., Toronto, have been incorporated, with a capital of $40,000, to carry on a foundry and machine shop and contracting business. The provisional directors include, C. A. Campbell, J. W. DuLaney and S. Campbell, Toronto.

The Dominion Tool Co., Peterboro, Ont., have been incorporated, with a capital of $100,000, to manufacture augurs, bits, gimlets, bolts, screws, rivets, etc. The provisional directors include, W. R. G. Higgins, P. J. Creedon and F. C. Cubitt, Peterboro, Ont.

The Haileybury Brick & Tile Co., Haileybury, Ont., have been incorporated, with a capital of $50,000, to manufacture brick, tile, clay, etc. The provisional directors include, A. J. Murphy, B. C. Beach, Haileybury, Ont., and D. McArthur, Kenmore, Ont.

The Standard Metal Manufacturing Co., Montreal ; capital, $18,000 ; to take over as a going concern the Standard Metal Manufacturing Co. Incorporators, F. G. Robinson, L. Seymour, H. W. Cooper, H. S. Vipond and F. T. Enright, all of Montreal.

The Gilmour Mining Co., Belleville, Ont., have been incorporated, with a capital of $300,000, to carry on a mining, milling and reduction business. The provisional directors include, F. Landenberger, W. Carnew, Belleville, Ont., and L. P. Smith, Syracuse, N.Y.

The Plantagenet Woolen Mills Co., Plantagenet, Ont., have been incorporated, with a capital of $20,000, to manufacture woolen and textile goods, etc. The provisional directors include, T. A. VanBridger, A. A. Fraser and D. M. Viau, Plantagenet, Ont.

The Canadian Smelting & Refining Co., Toronto ; capital, $2,500,000 ; to prospect for and deal in ores, metals and minerals. Provisional directors, J. D. Pringle, D'Arcy Grierson, Victoria Morrison, Alexander G. Robertson, W. Maxime Wallace, all of Toronto.

Haileybury Brick & Tile Co., Haileybury, Ont.; capital, $50,000 ; to manufacture and sell building material of all kinds. Provisional directors, A. J. Murray, Benson Clothier Beach, Haileybury, Ont.; Chas. F. McArthur, E. E. Wilson, Duncan McArthur, all of Kenmore, Ont.

Canadian Northern Systems Terminals, Toronto, have been incorporated, with a capital of $2,000,000, to construct oil tanks, pipe lines, steamboats, piers, docks, warehouses, factories, etc. The provisional directors include, A. J. Mitchell, F C. Annesley and L. W. Mitchell, Toronto.

The Canadian Northern System Terminals, Toronto ; capital, $2,000,000 ; to build and operate terminals, stock yards, oil tanks, elevators, smelters and ore furnaces. Incorporators, Gerard Ruel, A. J. Mitchell, J. B. Robertson, R. P. Ormsby, F. C. Annesley, L. W. Mitchell, all of Toronto.

The Canadian Smelting and Refining Company, Limited, Toronto ; capital, $2,500,000 ; to prospect for, own and develop mining lands and refine ores. Provisional directors : John Davidson Pringle, D'Arcy D. Grierson, Victoria Morrison, Alexander Godfrey Robertson, and William Maxime Wallace, all of Toronto.

The Dominion Tool Company, Limited, Peterboro ; capital, $100,000 ; to carry on the manufacture of augurs, bits and other tools and appliances for boring and drilling, bolts, rivets, screws, nails, and machinery for the manufacture of the same. Provisional directors : James Davidson, Francis Randolph, Joseph MacPherson, Patrick Joseph Creedon, Frederick Cromwell Cubitt and Francis Patrick McNulty, all of Peterboro.

Montreal Engineering Company, Limited; capital, $100,000; to carry on the business of electrical, mechanical and civil engineers and contractors to install machinery, equip plants, erect bridges, dams, etc., build canals, telephone and telegraph lines and general contracting. Incorporators: F. C. Clarke, A. J. Nesbitt, C. C. Giles, I. W. Killam and H. A. Porter, all of Montreal.

The Calkins Tile & Mosaic Co., Montreal; capital, $20,000; to manufacture and trade in any and every kind of marble, tile, terrasse and mosaic, concrete, granite, sandstones, limestones, clays, slates, plaster, terra cotta, lumber and all classes of structural iron and steel and building supplies. Incorporators, W. J. Henderson, Allan L. Smith, J. W. Hannah, A. C. Calder, John W. Graham, all of Montreal.

The Dominion Tool Company, Peterboto; capital, $100,000; to carry on the manufacture and sale of augurs, bits, gimlets, and all other tools or applianees used for boring or drilling purposes; also to manufacture and sell bolts, rivets, screws, and the necessary machinery for the manufacture of the same. Provisional directors; James Davidson, F. R. J. MacPherson, P. J. Creedon, F. C. Cubitt, F. P. McNulty, all of Peterboro, Ont.

Municipal Undertakings.

Paris, Ont., will install a duplicate lighting plant.

Ottawa will spend $28,000 in sewage construction.

Mimico, Ont., will borrow $7,000 for school purposes.

Clinton, Ont., passed a by-law for $53,000 for waterworks.

Listowel, Ont., will install its own electric lighting plant.

A new hospital will be erected by the town of Welland, Ont.

Olds, Alta., has passed a by-law to raise $12,000 for fire protection.

The new municipal power plant of Saskatoon, Sask., was put in commission recently.

The ratepayers of Estevan, Sask., will vote on a by-law to raise $92,000 for waterworks.

The civic asphalt plant for Ottawa will cost $14,800. A Buffalo firm's offer has been accepted.

The ratepayers of Kenora, Ont., will vote on a by-law to raise $75,000 for water power development.

A number of capitalists have applied to St. John, N.B., for the establishment of a car works in that city.

Public Works Department, Ontario Government, will erect a court house and registry office at Sudbury, Ont.

Neepawa, Man.—The Public Works Department, Ottawa, will erect and complete a public building at Neepawa, Man.

The Hamilton Electric Light & Power Company has made an announcement of the long-promised reduction in rates.

N. J. Ker, city engineer, Ottawa, is calling for bids for supplying and erecting an asphalt and bituminous paving plant.

Three money by-laws were passed in Vancouver: For new sewers, $300,000; for new roads, $100,000; for schools, $45,000.

The waterworks at Oshawa, Ont., recently added to their equipment a pump manufactured by the Smart-Turner Machine Co., Hamilton.

The town of Gravenhurst, Ont., is considering the granting of certain concessions to Hess & Co., who will erect a factory to cost $10,000.

The Kingston city council is to ask the Hydro-Electric Power Commission to quote prices for 1,000 to 2,000 horse power of electric energy, to be supplied at the city power station ready for distribution.

Two electric pumps, costing $50,000 and having a capacity of 10,000,000 gallons per day, will be installed in the city waterworks plant at Hamilton, Ont.

Brandon, Man.—Messrs. Dumas & Lochrane, of Ottawa, Ont., are the successful contractors for the $50,000 armory to be erected here. The proposed structure will be of brick and stone.

Winnipeg, Man.—The Winnipeg council has viewed favorably the establishing of public swimming baths. A by law will be considered at a future date which, if sanctioned by the people, will authorize the city council to issue debentures for $30,000, for the purpose of providing public baths.

The new municipal lighting plant for the town of Gravenhurst, Ont., was opened recently at South Falls, Ont. The plant cost $45,000, and consists of a 450 k.w. generator, driven by a water turbine of 750 horse-power capacity. Power can be supplied to Gravenhurst, at a cost of $7 per horse-power. This should be a strong inducement for industries seeking desirable locations.

The Ottawa electric commission will be ready to take over the lighting of the streets on December 20th, the date fixed in the notice given by the city to the Ottawa Electric Company, but it will be necessary to commence the work of changing the various circuits several weeks before that, as the civic plant will not operate the direct current system now in use by the electric company and the alternating current lamps will have to be installed circuit by circuit. It is expected that the installation will be fully complete by December 20.

Mining News.

Large shipments of iron are being made from the Atikokan district.

The Dominion Copper Co. will enlarge its plant at Boundary Falls, B.C.

The smelter of the Montreal Reduction and Refining Co., North Bay, Ont., will be in operation in a year's time.

The Pacific Coal Company, of Banff, Alberta, has let a contract for the erection of 240 coke ovens at the colliery at Hosmer.

The Del Nord Co. have located their head office at Sarnia, Ont. They are considering the erection of a large ore reducer in Quebec.

A. A. Cole, mining engineer, reports the discovery of promising quartz five miles from Temagami station, on the T. & N.O. Railway.

Charters have been issued to the Monessen Cobalt Mining Company, Limited, and the Oxford Prospecting & Mining Company, Limited, of Cobalt.

The Granby smelters are operating at fullest capacity at both mines and smelter, the entire battery of eight blast furnaces being in operation.

The Cape Breton Coal, Iron and Railway Company's colliery at Broughton, C.B., is being abandoned and a new boring is being made at a point four miles distant.

The Crescent Mines, Limited, Boundary, B.C., have installed an Allis-Chalmers-Bullock, Limited, electric compressor. Power is being furnished by the Greenwood City Waterworks Company.

Sault Ste. Marie is to have another large smelter, with a capacity of 125 tons per day. The capital of the new company, which is being promoted by O. Stalmann, Salt Lake City, is $1,000,000.

Another smelter is in prospect for Vancouver Island. The enterprise, it is said, will be undertaken by the Southern Cross Mining and Smelting Company, and £100,000 has already been subscribed for the work.

A Prospectors' and Mineral Interests Exchange has been organized in New Liskeard, with J. R. Lawless and Y. E. Taplin, of that place, as president and secretary, respectively. The object of the exchange is to eliminate middlemen's profits and brokers' options.

Canada's Yukon coal fields cannot be bought outright, but are leased for twenty-one years, and no concession of more than four miles square is granted on any terms. Only ten tons of coal per acre of the concession can be mined in any one year, and coal at the pit's mouth must be sold to actual settlers at $1.75 per ton.

A number of American capitalists and mineral experts are proposing to erect electric furnaces at Sydney, C.B., such as are now being used in France and Germany, to develop the iron ore mountain at St. George's, Newfoundland. The mountain rises to a height of 200 feet, and the assay of the ore, which is of a black magnetic variety, has shown as high as 60 to 65 per cent. metallic iron.

The Wilbur iron ore mine, north of Kingston, Ont., will be opened again to supply a Sault Ste. Marie firm for the manufacture of Bessemer steel rails. This ore is a high-grade Bessemer iron ore, low in phosphorus, and was one of the richest iron producing mines in the country till the Lake Superior mines were opened up. The better shipping facilities near Lake Superior made the mines there more accessable.

Building Notes.

A new armory will be erected at Strathroy, Ont.

James Worts, Toronto, will build a residence to cost $18,000.

The Toronto Rowing Club will erect a club house to cost $7,000

Building operations in the city of Hull, Que., for 1907, cost $275,000.

The Bank of New Brunswick will open a branch in Halifax, N.S.

Building operations at Barrie, Ont., for 1907, will approximate $150,000,

A Presbyterian church will be erected at Stettler, Sask., to cost $2,500.

New armories will shortly be erected in Calgary, Alta., at a cost of $40,000.

A. J. Strathy, Toronto, will build a four-storey store at a cost of $12,000.

A new police court building will be erected at Port Arthur, Ont., to cost $11,225.

Improvements to the Y.W.C.A. building, Simcoe street, Toronto, will cost $12,000.

Building permits were issued in Toronto from Oct. 7 to 15, to the value of $175,000.

The offices of the Traders Bank, at Guelph, will be enlarged, at a cost of $15,000.

The Y.W.C.A., Toronto, will erect an addition to their premises on Simcoe street, to cost $12,000.

The Bank of Montreal, Moncton, N.B., are calling for tenders for the construction of a branch there.

Montreal's new post office will cost in the neighborhood of $500,000. It will be completed in May, 1909.

The Royal Northwest Mounted Police barracks at Lethbridge, Alta., will be improved at a cost of $10,000.

The Canadian Bank of Commerce are erecting a new building at Kamsack, Sask., at a cost of about $10,000.

W. & D. Dineen, Toronto, will erect a factory at the rear of their premises, for the cutting and making of furs.

Architects have prepared plans for a $20,000 printing office for the Compagnie Action Societe Catholique, Quebec, Que.

The corner-stone of the new school at Westmount, Que., was laid recently. The building will cost about $100,000.

The new building for the Imperial Bank at Edmonton will cost $90,000. It will be completed in the near future.

The congregation of St. Joseph's church, Sydney, N.S., will erect a large edifice to replace the one recently destroyed by fire.

D. Spencer, Limited, Vancouver, B.C., have taken out a permit for the erection of a new store and arcade, at a cost of $240,000.

Building permits to the value of $385,700 were issued in Stratford, Ont., during September. The new G.T.R. shops, alone, will cost $360,000.

The Bank of Hamilton has applied for a permit to erect a three-storey bank building at the corner of Ossington avenue and College street, Toronto, to cost $25,000.

The Masons of Alpha Lodge, Toronto, have voted to join with other lodges in the erection of a new Masonic hall, to be built in the northwestern part of that city, at a cost of $60,000.

The number and value of building permits in Toronto for September has decreased considerably in comparison with September, 1906, although the aggregate for the year, so far, is well above that for the same period last year. The total in September was $550,000, but the $200,000 permit for the Alexandra theatre had been added to this, and thus the total is $750,000. This is $152,803 below the figure for September, 1906, which was $902,803. The permits issued so far this year amount to $12,204,000, as compared with $9,566,000 for the same period of 1906.

Railroad Construction.

Valuable coal beds have been found by the G.T.P. in British Columbia.

The C.N.R. are preparing to build a new station at New Westminster, B.C.

The C.P.R. has commenced the re-timbering of the trestle of the Interprovincial bridge.

The Esquimalt and Nanaimo Railroad is spending $100,000 in improvements on their road.

The Michigan Central Railway Co. is to construct a line from Charing Cross, Ont., to Chatham, Ont.

The Grand Trunk Pacific has 140 miles of track ready for Government inspection west of Portage la Prairie.

The C.N.R. intend increasing their coal docks at Port Arthur, Ont. The capacity of the docks when completed, will be 600,000 tons.

Work on the proposed railway from Port Simpson, B.C., to Port Churchill, on the Hudson Bay, will be commenced next summer.

P. & J. Powers & Co., Ottawa, have completed six large locomotive boilers for the C. N.R. These are the first locomotive boilers made at Ottawa.

The Canadian Pacific has decided to make Grand Forks, B.C., a divisional point and will erect roundhouses, repair shops and yards, at an expense of $100,000.

Welland Pipe Works.

The Page-Hersey Company have started operations on their new plant at Welland, Ontario. This new mill will manufacture pipe in sizes from four to eight inches. The work of construction is being carried on by the Berlin Construction Co. The buildings adjoin the works of the Ontario Iron & Steel Co., and the products of these works will be used in the manufacture of pipe.

The building for the lap weld furnaces will be 200 feet long, with wings at each end 380 feet long and 50 feet wide. The wings will contain the storehouse, thread-testing plant and overhead crane runway. Between the two wings will be a separate building for machine shop, 33x60 feet, and socket shop, 33x180 feet. Additional to this will be the gas producer house, 35x66 feet.

A Steady Growth.

Quebec city, in spite of the set-back owing to the Quebec bridge disaster, is showing fairly good progress. A strong evidence of this growth is a walk through the various departments of the extensive establishment of the Mechanics' Supply Co., in St. Paul street, Quebec. The steady progress made by this firm is evident in the large stocks carried and in the additions to their building. The electrical department contains many exclusive lines, and their showrooms throughout are the essence of taste, depicting many uncommon lines.

New Locomotive Works for Lachine.

A by-law to give a bonus of $50,000, exemption from taxes for twenty years, and reduction in the water tax to an English syndicate to establish a locomotive works in the town of Lachine was voted on, on October 21, and carried by 288 to 21. For this cash bonus, the syndicate will build a plant costing $2,250,000 and employ 500 men at the end of the first year, and 1,500 at the end of the third year.

Big Power Plant on the St. Lawrence.

Another immense power plant was discussed before the International Waterways Commission when a proposition for the development of electrical power on the St. Lawrence river, near Cornwall, at a cost of $20,000,000, was put forward by the St. Lawrence River Co. of Canada, and the Long Sault Development Co., of United States. The St. Lawrence Co. at present supplies Cornwall with light power, but its capacity of 1,250 horse-power is exhausted and the new plan provides for 50,000 horse-power. The Canadian concern will invest $5,000,000, and the American $15,000,000 in the scheme.

Large Smelter for Toronto.

D. D. Mann, of the firm of Mackenzie & Mann, has sent a definite offer to the city of Toronto to build a 1,400-ton smelter in Toronto, in return for a grant in fee simple of some waste lands known as Ashbridge's Bay. This marsh or bog extends to 1,377 acres, and Mr. Mann has made an offer to use part of this marsh to establish works, which will eventually employ 15,000 men. The Moose Mountain Mining Company is behind the scheme. The capital of this company is $2,500,000 paid up. At Moose Mountain, in Hutton township, there is an unlimited supply of raw material of good quality. The intention of the company is to make a beginning in smelting and to put up a thoroughly equipped modern plant for the smelting and making of pig iron, and to add to it gradually so that in the end a very large iron and steel industry would be established. Eventually about 1,000 acres would be required for the entire plant, as the smelter works will be followed by a steel plant, rolling mills, steel car buildings. The allied industries would take up the manufacture of steel billets, steel bars, angle iron, rolled billets for shipbuilding, and steel and iron of all kinds for various industries, while the manufacture of steel rails is definitely in view. As soon as the smelter works are in operation, the company will have 700 tons of slag per day to be used in filling-in, but the filling for the smelter works would have to be taken in by rail and water. This is an opportunity to make Toronto the Pittsburg of Canada. The work of construction will begin at once should the city accept the offer.

PERSONAL MENTION.

Mr. J. W. Prophie, formerly master mechanic for the Atlantic Steel Co., Atlanta, Ga., has accepted a similar position with the Ontario Iron & Steel Co., Welland, Ontario.

Mr. Walter B. Snow, for many years connected with the publicity department of the B. F. Sturtevant Company, has resigned and opened offices at 170 Summer St., Boston Mass., as a publicity engineer. He will do all kinds of work in the way of publicity for manufacturers of machinery and allied products.

AMERICAN FOUNDRYMEN'S ASSOCIATION.

The annual convention of the American Foundrymen's Association will meet in Toronto about the first week in June, 1908. Over fifteen hundred attended the convention in Philadelphia this year and a profitable time was spent. Full information in regard to the Canadian conference will be given in a succeeding issue.

ENGINEERS' CLUB OF TORONTO.

At the meeting of the Engineers' Club on Oct. 10, the subject for discussion was, "Principles of Professional Conduct for Guidance of Engineers," introduced by Mr. A. B. Barry, who said that professional ethics simply consists in the exercise of that honorable feeling and courteous manner which gentlemen extend to, and expect from one another and there is no code, written or unwritten law, which can justify or absolve an engineer from doing that which his own sense of honor and integrity tells him is unprofessional. The engineer is, or should be, from the nature of his calling, a strong-minded man, one who seeks to control the forces of nature for the benefit of man. An engineer should obtain all the information he could, but should not tell trade secrets while under salary. A discussion arose as to the proper place for controversy, and while some thought the public press was the best place, yet a general feeling prevailed that the proper place is in the technical press and trade journals.

At a meeting of the Toronto branch of the American Institute of Electrical Engineers, held at the Engineers' Club, Toronto, on Friday, October 11th, the following were elected: Chairman, K. L. Aitken; vice-chairman, W. A. Bucke; secretary, L. W. Pratt; executive committee, H. W. Price, Edw. Richards and W. G. Chace.

We manufacture ***CRANES, PUMPS, CONDENSERS, Etc.,*** and solicit your correspondence, whether you want to buy or whether you want information.

MANUFACTURERS AND MANUFACTURERS' AGENTS.

It will pay you to watch our condensed column each month. There are many money-making propositions brought to your attention here. You may find just what you are looking for.

RATES

One insertion—25c. for 20 words; 1c. a word for each additional word.

Yearly rate—$2.50 for twenty words or less, 10c a word for each additional word.

The above does not apply to notices under the head of "Machinery Wanted." These notices are inserted free for subscribers.

BUSINESS CHANCE.

FOUNDRY FOR SALE—In a thriving Ontario town of five thousand inhabitants; is a going concern, employing from ten to fifteen hands, and does a general foundry business; no opposition within ten miles, and there are numerous orders now on hand; owing to a dissolution of the partnership the business must be sold at once. Apply Box 45, CANADIAN MACHINERY, Toronto.

FOR SALE.

FOR SALE—The Canadian patent rights on a valveless pneumatic hammer, proved by actual test to be superior to any hammer at present on the market; an arrangement can be made to manufacture same on royalty for Canadian market. Apply Box 39C, CANADIAN MACHINERY, Toronto. (9)

FOR SALE.

BELTING, RUBBER, CANVAS AND LEATHER, Hose, Packing, Blacksmith's and Mill Supplies at lowest prices. N. Smith, 138 York Street, Toronto. (2tf)

MARINE gasoline engine castings, with blue print and full instructions, etc.; 2½, 4, 6 h.p.; also complete finished outfits at $65 up; catalogue, Krug & Crosby, Hamilton. [10tf]

OWING to the installation of a new water-power plant, the town of Gravenhurst has for sale the following electrical machinery:—One 100 k.w. 2,400 volt, 66 cycle, 2 phase, 1,000 R.P.M. belted type S.K.C. alternator, complete with rheostat, phase regulators and field rheostat.

ONE 2½ K.W., 125, volt 1900 R.KM., shunt wound, C.G.E., exciter; complete with. pulley, base and rheostat.

ONE blue Vermont marble switchboard panel, 48 x 60 x 1¼, complete with pilot lamps, ammeters, voltmeter, switches, fuses, rheostat mountings, etc., for the control of the generator and the exciter.

ONE tandem compound, belted type Wheelock engine, 13" diameter, L.P. 22" x 30" stroke; this engine complete with Inglis independent condenser, feed water heater, and one Smart-Turner duplex boiler feed pump, 5¼ x 3½ x 6 in., all necessary oil cups, lubricators, line shaft pulleys, etc.

ONE 14" double-ply leather belt; one 12" ditto, and one 18".

ONE belt drum Goldie & M'Culloch condenser.

FOR further paeticulars apply to W. H Cross, Secretary Electric Light Commission.

SITUATION VACANT.

WANTED AT ONCE—Superintendent and mechanical engineer for machine works manufacturing gasoline engines and general machine work; one familar with modern methods, capable of making estimates, drawings and producing work at minimum cost; give full particulars of qualifications, experience, age, nationality and aalary. Apply to Brandon Machine Works Co., Ltd., Brandon, Man. [9]

SITUATIONS WANTED.

ADVERTISER, shortly emigrating, seeks position as correspondence clerk and accountant. Well up in all details of engineering and allied business; ledger balancing, shorthand and typewriting; excellent references. Lister, Ipswich Road, Ardleigh, Colchester, Eng.

WANTED—Position as purchasing agent or correspondent for manufacturing firm by a young man at present employed in a similar capacity by one of the largest manufacturing concerns in Ontario; has had long experience in these lines, thoroughly understands all branches of office work and can furnish best of references. Address Box 43, CANADIAN MACHINERY, Toronto. [10]

MECHANICAL engineer (25) seeks position; experienced in construction of modern copper, zinc, smelting works, machinery furnaces, etc.; general engineering, gas, steam engines, suction and pressure gas plants; structural steel, etc.; reliable, energetic; good references. Box 27, CANADIAN MACHINERY, 88 Fleet St., London, Eng. [10]

AGENTS WANTED.

A Firm of Chemical Engineers

are requiring first-class agents in the large cities of Canada. Apply to W. J. Fraser & Co., Ltd., Chemical Engineers, 98 Commercial Road East, London, England. [11]

CANADIAN MACHINERY

Montreal Toronto Winnipeg

THE CANADIAN TURBINE WATER WHEEL

We have not expanded the discharge of our turbines, as we find the results given by our combined impact and reaction runner to be vastly superior to those obtained from turbines of the expanded discharge type. Do not sacrifice your water power. We can save you 20 to 30 per cent. of your water and at the same time give you a much more satisfactory drive.

CHAS. BARBER & SONS, Meaford, Ont.

Turbine Water Wheels, Governors and Gearing only

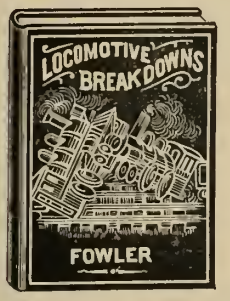
PRACTICAL LITERATURE

For Electricians, Scientists and Engineers

All orders payable in advance.

Locomotive Breakdowns

Emergencies and their Remedies



by Geo. L. Fowler, M.E.

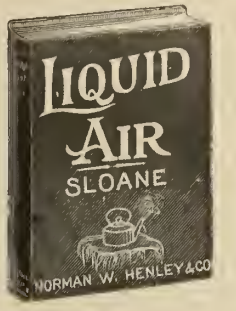
Price $1.50, Postpaid.
250 Pages, 96 Illustrations.

This book is an up-to-date catechism treating on all classes of accidents which may happen to locomotive engines and giving the remedy to be applied. Accidents to the Valves, Cylinders, Valve Motion, Running Gear, Compound Locomotives, Boiler Troubles are treated separately and fully. It tells what should be done in any emergency.

Liquid Air

and the

Liquefaction of Gases



by T. O'Conor Sloane, A.M., E.M., Ph.D.

Price $2.00, Postpaid.
365 Pages, Fully Illustrated.

This book contains the full theory, history, biography and bibliography of the subject from the earliest times, as well as a description of all the wonderful experiments performed with it, showing how liquid air is carried hundreds of miles and handled in open buckets. It also tells what may be expected from it in the near future. Although a work of scientific interest and authority, it is intended for the general reader.

Engine Runner's

Catechism

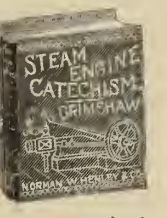
by Robert Grimshaw, M.E.

Price $2.50, Postpaid.
354 pages, Profusely Illustrated.

This work gives complete descriptions of the general characteristics of various well-known makes of engines, followed by details of shipping, making foundations, erecting and starting, and the specific instructions as to the adjustment of special makes. Every engineer will find in this volume more really practical and useful information than is to be found anywhere else within a like compass.

Steam Engine

Catechism



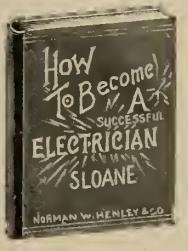
by Robert Grimshaw, M.E.

Price $2.00, Postpaid.
413 Pages, Fully Illustrated.

This book is a series of nearly 1000 direct, practical questions and answers; in fact it contains every essential question on the Steam Engine with its answer. Leading engineers have recommended it as a valuable educator for the beginner as well as a reference book for the engineer. It is intended for

EVERYONE INTERESTED IN STEAM.

How to Become a Successful Electrician

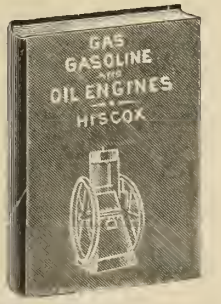


by Prof. T. O'Conor Sloane, A.M., E.M., Ph. D.

Price $1.00, Postpaid
200 Pages, Bound in Cloth.

Every young man whose ambition it is to become a successful electrican should read this book. It is the clearest and most practical book on the subject ever published. Its 19 Chapters include Mathematics, Physics, Chemistry, Electricity at Home, Drawing, Electrical Factory Work, Mechanical and Steam Engineering, the Manufacturing and Constructing Engineer, Inventing, Original Investigation, etc.

Gas, Gasoline and Oil Engines



by G. D. Hiscox, M.E.,

Price $2.50, Postpaid.
450 Pages, 351 Illustrations.

This book is a thorough treatise on the construction, installation, operation and maintenance of gas, gasoline, kerosene and crude petroleum engines. It is the new rewritten enlarged and revised 15th edition of this work giving general information for everyone interested in the popular motive power, and its adaptation to the increasing demand for a cheap and easily managed motor requiring no licensed engineer.

"PARTAMOL"

The Acknowledged Standard Parting for Parting Molds

The Money Saver and Profit Producer

"Success means willingness to put aside the old for something better."

Partamol is the something "best" in parting compounds. It turns out a perfect mold with every line true to pattern. Allows of easy and perfect "slicking" of the mold. The results from its use will astonish you. The price will please you. Sample on request.

DOGGETT'S PERFECTION PARTING

GUARANTEED TO PERFECTLY PART UNDER ANY AND ALL CONDITIONS

For Straight and Difficult Lifts Sticky Patterns Slanting Copes and Deep Chasings

Permits Swabbing and Slicking.

Will not Burn off the Face of the Mould, Wash or Cut.

SUITABLE FOR BRASS, BRONZE, IRON, ALUMINUM

Manufactured by

STANLEY DOGGETT

101 Beekman Street . New York City, U. S. A.

DISTRIBUTING AGENTS

DETROIT FOUNDRY SUPPLY CO., Windsor, Ont., and Detroit, Mich.

ALSO MANUFACTURE

CHARCOAL and CHARCOAL FACINGS AND ALL GRADES OF SOAPSTONE FACINGS

Woodison Prepared Clay

Next to graphite, the most fire-resisting element known.

For daubing your cupola, ladles, or for setting fire-brick, is unexcelled. Will give better results than three times as much fire-clay.

The price is right, and a barrel can be had for trial. If satisfactory, pay for it; if not, keep it with our compliments.

With us taking all the chances, you should not hesitate sending the order to-day.

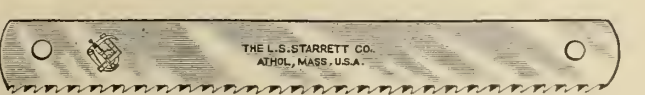
STARRETT TOOLS

ARE THE STANDARD

FOR ACCURACY, WORKMANSHIP, DESIGN AND FINISH

HACK SAWS



These blades are made of the finest grade of steel. The teeth are sharp, with square cutting points, and evenly set. They are tempered by our improved process, which leaves them hard and tough, so that they will not "shell off." They are too hard to file. The set of the teeth is just enough to insure a free, smooth and rapid cut, removing no more stock than is necessary.

LOOK FOR THIS MARK ***ON SAWS AND LABELS***

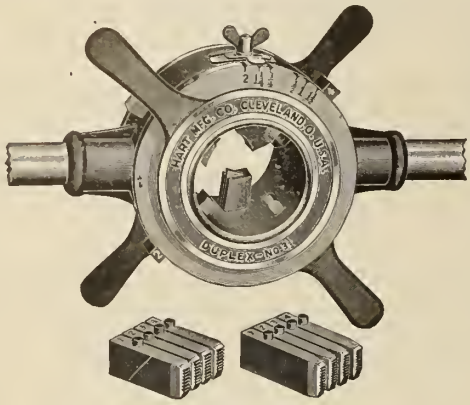
Send for free Catalogue No. 173 and Supplement, 192 pages of the best of Fine Mechanical Tools

THE L. S. STARRETT CO., ATHOL, MASS., U. S. A.

HART'S ADJUSTABLE DIE STOCKS

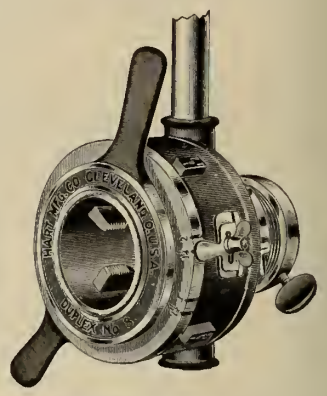
For Pipe "DUPLEX" For Bolts

Their instant adjustability, requiring only the hand and no wrench, makes tight joints always obtainable. Perfect threads are made with a single cut. After cutting a thread the dies may be opened instantly and the stock removed, avoiding the running back over the threads, an operation which frequently strips the threads just cut. The cutting edge of the dies is on an individual tool by itself, and can be sharpened by simply grinding the face, as you do a chisel. These stocks are fitted with self-centering guides. We can supply them with a cutting off device if so desired.



No. 3½
Range ½ to 2-in., for Pipe.

Ask for our prices



Ratchet Pattern, No. 8
Range 1 to 2 in. Pipe, one or two handles may be used.

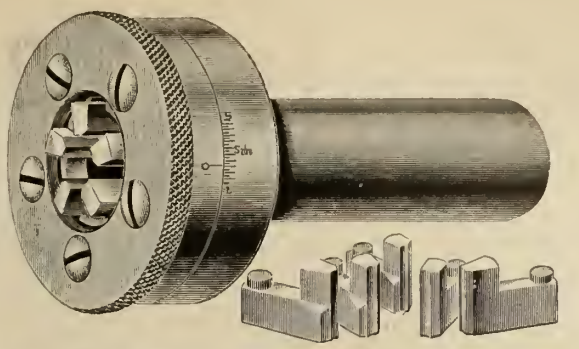
Tools that cannot be surpassed, that cannot be equalled. Tools for all kinds of Mechanical Work.

Rice Lewis & Son

LIMITED

TORONTO



GEOMETRIC ADJUSTABLE HOLLOW MILLING TOOLS

If you wish to secure economy in Brass Finishing, it will pay you to investigate the labor saving qualities of our ADJUSTABLE HOLLOW MILLING TOOLS. No other device will so rapidly produce accurate uniform diameters. They are made in various sizes, and can be used on Automatic Screw Machines, Hand Turret Lathes, or rotated in any way desired. The index permits rapid setting to any diameter within its capacity and equally quick change from one diameter to another. They will reduce work of any length, will mill close to shoulder, and as the sharpening of the blades is done only at the outer edges, there is very little time lost in regrinding. If you are finishing brass work of any kind you will be interested in a full description of this tool.

Last month three hundred and twenty-nine magazines and periodicals reached the Editorial Department of the BUSY MAN'S MAGAZINE. Each of these was carefully ransacked by a competent editorial staff, and the most INTERESTING, LIVE, UP-TO-DATE articles selected and reproduced in the

BUSY MAN'S MAGAZINE

Think of the value of this single number of the BUSY MAN'S to you—containing, as it does, the cream of the world's periodical press.

You will not have to turn over a dozen pages to get one that interests you. Every article is interesting, selected, as it was, from a leading magazine because it was the best in that publication.

Yet this many-in-one magazine is only $2 per year.

We have a special offer which will interest you.

The Technical Publishing Co., Limited
30 Cross St., MANCHESTER, ENGLAND

DO YOU KNOW that there is no other magazine in the world that covers the fields of engineering and technology to the same extent or in such a useful literary way as TECHNICAL LITERATURE, and that no other appeals equally to specialists and the general reader in so many branches of the profession? It has become a most valuable companion to such professional men as

Architects	Engineering Students	Hydraulic Engineers	Mechanics	Patent Attorneys
Chemists	Factory Managers	Iron and Steel Makers	Metallurgists	Power Consumers
Civil Engineers	Foundrymen	Irrigation Engineers	Mining Engineers	Railroad Engineers
Contractors	Gas Engineers	Machine Tool Makers	Municipal Engineers	Sanitary Engineers
Draftsmen	Heating, Lighting and Ventilating Engineers	Marine Engineers	Oil, Paint and Varnish Makers	Steam Engineers
Electrical Engineers		Mechanical Engineers		Water Works Engineers

AND OTHERS INTERESTED IN TECHNICAL WORK OR STUDY

Such men may be considered as forming the backbone of the citizenship of the country. They are the men who do things, and who control the expenditure of millions of dollars, involving the purchase of all kinds of material and machinery. If you have anything to offer them for business or pleasure, advertise it in TECHNICAL LITERATURE. *Let us show you the scope, vitality and the power of our circulation.*

ONE ADVERTISER WRITES: "Your magazine is a good one and sure of success. It is going to be looked over by a good class of readers, and our advertisement will not be lost in a mass of ill-digested matter."

ADVERTISING RATES SENT ON APPLICATION

Subscription price, $2.00 a year to United States or Mexico; $2.25 to Canada; foreign countries, $2.50. Single copies, 20 cents.

¶ The illustration shown is one of our latest. The success of the W. W. Sly Mfg Co.. in manufacturing cleaning room equipments has attracted the attention of people without the ability to create or design goods that are required for that purpose—(we consider this a compliment). If you compare their catalogue with ours, you will see that they have even copied our catalogue. If you compare their Mills with ours, you will see that it is the Mill that we built a number of years ago, or a similar mill to our present Mill, with all the vital improvements left out. We are constantly imroving our Mills. Buying them means that you are from one to five years in advance of our competitors.

Let us figure on your Cleaning Room Requirements.

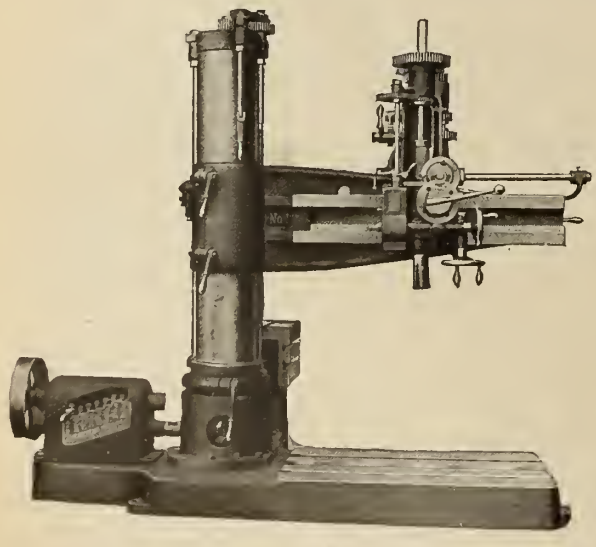
DURABILITY



Improved Plain Radial.

No matter how many cost saving features a machine may possess it will prove a poor investment if frequent repairs are required.

The New Bickford Radial

is designed to run continuously. The bearings are large, speed of all shafts is low and all parts are commensurate with the work required of them.

This is another of those valuable cost reducing features.

Our Radial catalog tells the rest.

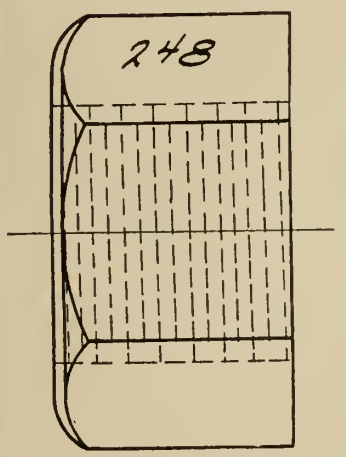
Cost Reduced—Profits Raised!

The Cleveland Automatic reduces cost by turning out duplicate parts quicker than any other machine. Moreover, every piece of work turned out on a Cleveland is absolutely accurate. If you have a Cleveland you can figure closer and make more money than the man who hasn't.

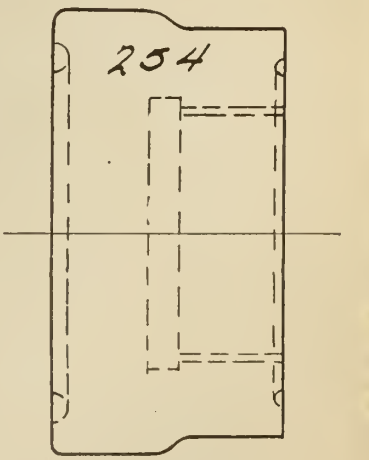
Let us estimate on what your work would cost on a Cleveland.

"The Pre-eminence of the CLEVELAND is indisputable"

Read these two examples, showing how quickly and cheaply the parts were manufactured.



Piece No. 248—Material, semi-finished nuts, using our Tilting Magazine Attachment, on a 2 in. 3-Hole Cleveland Automatic Turret Machine; drawing full size; output per hour 55; this means facing and tapping; actual cost of labor from 1 to 1⅓ mill for each piece. Send along samples or drawings. We guarantee our outputs. One man can operate from 4 to 6 machines.



Piece No. 254—Material, Steel Casting, using our Tilting Magazine Attachment on a 2¼ in. Cleveland Automatic Turret Machine; drawing full size; output per hour 26; this means all operations for completing this piece; actual cost of labor from 2 to 2½ mills for each piece. Send along samples or drawings. We guarantee our outputs. One man can operate from 4 to 6 machines.

As we have no Canadian Representative, we Solicit Correspondence and orders direct.

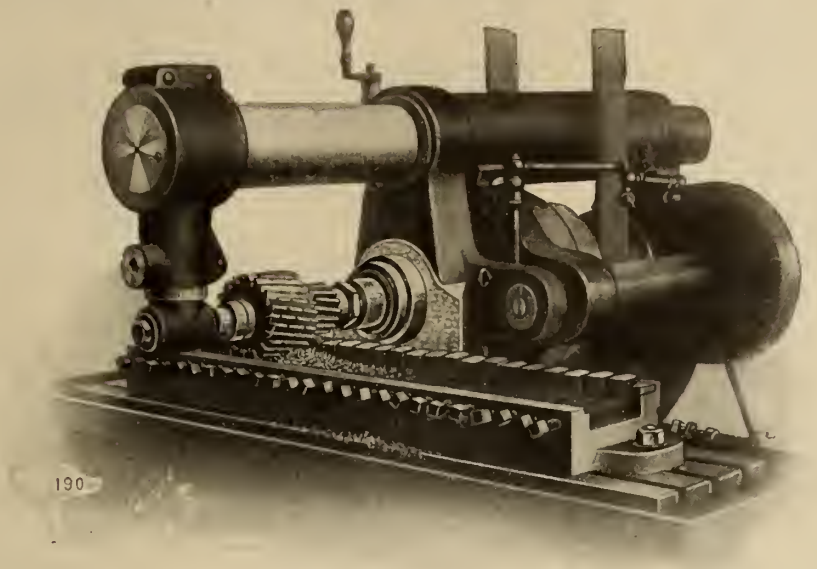
This style of press has a GRADUATED ADJUSTMENT, and is better adapted than any other design for HEAVY BLANKING, PUNCHING, PERFORATING, FORMING, etc.

They are SYMMETRICALLY DESIGNED, and the FINISH is equal, if not SUPERIOR, to any imported.

We manufacture a full line of PRESSES, TINSMITHS' TOOLS, CANNING MACHINERY, etc.

The Brown, Boggs Co.
LIMITED
Hamilton - - Canada

REPETITION WORK



A great many shops are proving to their own satisfaction, that it no longer pays to finish small machine parts on the old-fashioned Lincoln type of miller. We can tell you of some large shops that have replaced their Lincoln pattern miller equipment with Cincinnati No. 2 Plains, and are getting out more work and better work, because these machines are more powerful and more convenient to operate. Note for example, this grey iron casting 1⅛ in. wide. Twenty-four of these are held in a string jig and finished at one cut with a gang of cutters 4½ in. and 3 in. diameter as shown. The total width of cut is 3¾ in., depth of cut ⅛ in. —table travel 1⅞ in. per minute. The finished pieces are accurate within .001, ready for assembling without additional handwork.

This machine finishes 24 of these pieces in 15 minutes. Let us figure on millers for your work. WE ARE MILLING SPECIALISTS.

The Cincinnati Milling Machine Company

CARBORUNDUM

GRINDING WHEELS

MADE AT NIAGARA

USED THE WORLD OVER

There are something like two hundred thousand different sizes and shapes and grades of Carborundum Grinding Wheels—

There are little bits of wheels for the use of jewelers and dentists and there are wheels 3 feet high for grinding car wheels and other big work of that sort—

There are wheels for working marble and granite that do more work and better work than steel tools ever did, and that have practically replaced steel tools in many establishments—

And then there are wheels to do every other sort of grinding work that anybody ever thought of—Carborundum.

Does the work faster and better—
Accomplishes more work in a day—
And lasts more days before wearing out than any other abrasive material on earth.

We are constantly making special wheels for special purposes—

We have experts here whose sole duty it is to solve grinding problems —

If you will write us about your grinding requirements we will be glad to tell you just what Carborundum can do for you.

The Carborundum Company
Niagara Falls, N.Y.

IT PAYS TO INSTALL THE BEST

POWER PRESSES

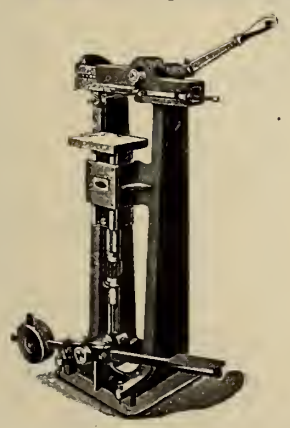
The many exclusive features embodied in the type shown above make it so much superior to the next best that there is no comparison.

Write for prices and particulars on **Presses, Dies, Tools and Special Machinery.**

W. H. BANFIELD & SONS

120 Adelaide Street West, TORONTO.

No. 3 Marking Machine



This machine is designed to mark by means of steel dies letters, numbers, trade-marks, monograms, etc., on either flat or round metal surfaces, such as axes, piatol barrels, files, table cutlery, twist drills, taps, dies. reamers and a great variety of work.

Our principle of bringing a slight line contact of die with work insures light wear on dies and makes it possible to mark hollow tubes, handle, chuck and valve work which would not stand the blow of a punch or drop press.

Correspondence and sample of work solicited. Machine sent on approval to responsible parties.

MACHINE TOOLS

¶ We wish to call your attention this month, Mr. Purchaser, to a few points in regard to the buying of Machine Tools, and to acquaint you with our fixed purpose to supply your wants to a degree of accurate attention to detail, promptness, fairness, soundness of judgment and reliability that will make you our friend or fix our present friendly relations more firmly than ever.

¶ This country is developing with a rapid but steady and healthy growth. Competition is becoming keener every day. You must reduce your manufacturing cost to keep pace with the times, with altered conditions, and so increase your profits. The time has come, when, in justice to yourself, you must make the main issues in the purchase of Machine Tools: What work will it produce? How fast, how accurate, how cheaply will it produce it? Not how cheap a machine can I buy?

¶ We have the finest agency organization of cost cutting machinery in the Dominion, and will be glad to offer many helpful suggestions which will put money in your pocket if you will write or call on us. Your satisfaction is our credit. Do you recognize that? We do, and on your satisfaction we must depend for our profit.

¶ A heavy duty, rapid production machine for occasional use would be foolish extravagance, as anyone will admit, but an ordinary standard machine for continuous manufacturing would be even more costly, as the saving in purchase price would soon be lost, after which the machine becomes a continuous loss to you as long as it is used. Why? Decreased production. This is the ABC of modern manufacturing, but does your factory demonstrate your faith in this fact, Mr. Purchaser? The right machine for each class of work is what we offer, a principle to which we rigidly adhere, for your satisfaction is our credit, as we said before.

¶ Our expert will call on you if your factory is not too far distant, or, if so, we will ask you to write us a minute description of your needs and conditions and let us prescribe. We are selling agents for metal working machine tools, transmission, contractors and mining machinery, electric, steam, producer or other gas and gasolene power in any units.

Accurate Drilling and Reaming on a Manufacturing Basis

The Development and Rise of Jigs in the Machine Shop—A Milling Machine Knee as an Example.

BY JOHN EDGAR

The progress that has been made in the production of small parts for various kinds of machinery has placed accuracy and low cost of production on a level. Up to a few years ago they did not in but few instances travel hand in hand, and in those few scattered cases the methods were considered trade secrets.

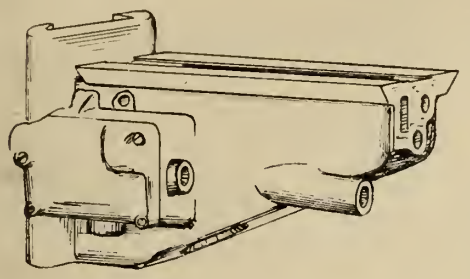

Fig. 1—The Knee.

The large run that the bicycle had and the competition that grew up in that industry are responsible for many of the modern forms of manufacturing practices and were in the main the real beginning of the new era in the manufacturing world in relation to the production of high class work at a low cost.

How has all this been accomplished? In the broad sense, by employing manufacturing methods in the production of the machinery, that is, by producing as many parts of a peculiar type as possible at a time. It has been found that by following that course and by the introduction of special tools and fixtures, the work was not only produced much quicker and cheaper, but much more accurate than by the old method of producing each part separately and fitting same in position. Similar parts, though supposed to be duplicates, were more often not duplicates when fitted in this manner. In the new system this is taken into consideration and each part is a duplicate of any one of a hundred similar parts, and anyone may be replaced by another due to the narrow limits that they are allowed to differ in passing the inspector. The new method is then based on the interchangeability of the details which go to make up a machine.

Where, on the introduction of this system we heard grave murmurs against it, we now find it to be one of the greatest recommendations that a manufacturer can have: "That he manufactures on the interchangeable plan." In fact, it is such a recommendation that we find that those who were loud in words against the system on its introduction and who have in no way changed their methods other than by a few minor jigs, if they may be called such, supporting the new system.

What a vast difference this system has made in all branches of manufacture. It is touching every nook and corner, and the firm that tries nowadays to live outside of its border finds itself drifting further and further backward until it must either change its methods or drop out of sight completely.

Progress in the New System.

While this system had its inception in the small arms plant it, as mentioned above, was really nourished into robust existence by the bicycle industry. In the small arms plant and also in the typewriter factory, it was used in the production of very small parts that go

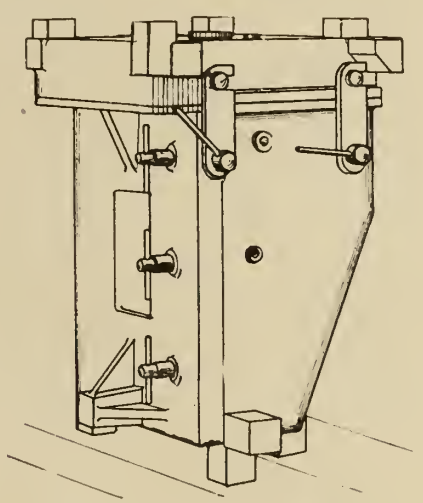

Fig. 2—The Jig Closed.

to make up these machines, and its introduction made it possible to produce good working machines at a reasonable price, but in the bicycle business it was applied to much larger parts and to parts that required much greater accuracy in their make up. This opened the eyes of manufacturers in other lines, and so we have to-day the modern system so much in vogue that one wonders how it was that it was not instituted earlier. But such is progress.

The machine tool manufacturer, strange to say, was among the last to take up this system, and when we think that in his line where everything is made for accuracy, we may ask why he should be among the last to employ such an advance in methods. However, he has at last laid aside his badge of conservatism and come forth with some wonderful changes in his large line of manufacture, both in his own methods and in the methods he offers for sale in the machines he produces. His first advance was in the use of drill jigs and fixtures. With these he was able to produce parts in which the different holes were located properly by means of fixed bushing, thus automatically locating them in relation to a proper surface and with each other. From this we find him using them (jigs and fixtures), on his milling machine, in conjunction with gang cutters, thus producing duplicate parts in this relation. The work being located from some important bearing and the cutters being set producing surfaces in proper relation to that bearing. He then goes still further and uses similar methods for holding his heavier work on the planer. Here he was in a different position with regard to the actual machining operation, because he must work with a single pointed tool capable of producing none but plain surfaces. In order to overcome this handicap he uses a dummy gauge by which to set his planer tool, thus, had he to plane a lathe bed-ways. He first had a dummy made of a profile exactly similar to that desired on the work in hand and which clamped to the plate of the machine, the cutting edge of the tool was set to this, ensuring, within narrow limits, duplication in each series of parts planed under the guidance of any gauge.

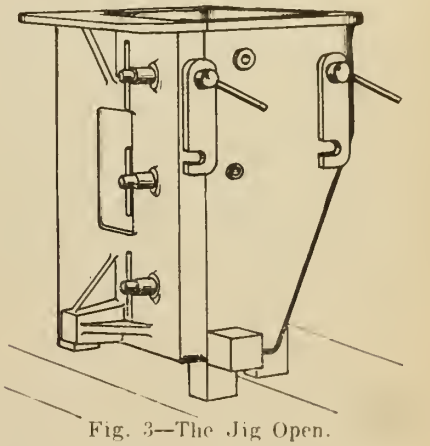

Fig. 3—The Jig Open.

The system has so increased in application that it is now used in the manufacture of the heaviest classes of machinery.

The Milling Machine Knee Shows the Advancement.

So much dependence is placed upon holes and their location in the design and

construction of machinery that the branch of the trade which has to do with producing them has received more attention than any other single branch. For that reason we find it far in advance of all other departments in the quality of work produced under the new system of things. As an example, of what is being done in the drilling and reaming of holes accurate as to size and alignment by means of jigs and special tools, the case of the milling machine knee, shown in Fig. 1, will be described and the methods used and the results obtained pointed out.

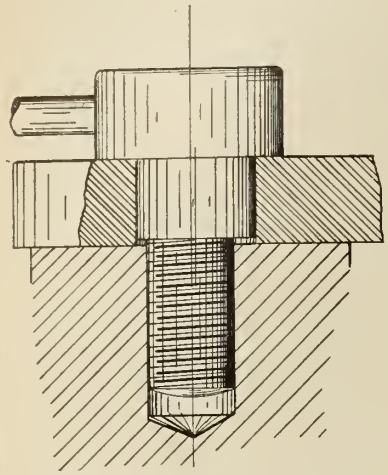

Fig. 4—The Eccentric Clamp.

This casting is rather heavy for easy handling and on account of its size it is liable to lead one into the temptation of trying to do the drilling by using a number of detached jigs that might be made to care for one or two sets of holes irrespective of the proper relation with holes in other locations. When possible the most economical method to pursue, in almost any case of drilling, where a number of holes have to be drilled, is to use a box jig, the drill bushings being fixed in the sides of the box. This style jig construction gives the greatest rigidity and reduces the liability of having the holes thrown out of line due to the casting changing in seasoning or from rough usage. Figs. 2 and 3 show the jig used in our example, the former figure showing the box closed and ready for use, while the latter shows the jig with cover removed and realy to receive the work.

Operations on the Knee.

Before being placed in the jig the knee is planed all over and the cover for the box on the side is drilled on. As there is a bearing in this cap which carries a shaft and gear which latter meshes with a train of gears on the shaft in the box, the bearing in the cap must bear a fixed relation to the hole in the box. Were the cap or cover drill otherwise the joining surfaces of both cap and box would require an extra amount of caution which is eliminated. This is one place where the principle of interchangability is not carried into practice, and such being the case the cover and knee must go in pairs. The two holes shown through the front end of the knee are for the cross screw and centre shaft, and line with holes in the rear end. These holes bear a certain relation to the carriage that carries the table and which slides on the top face of the knee. Since the motion to the lead screw is obtained from the centre shaft through a vertical shaft connecting both screw and centre shaft, we have a hole in the carriage which must line with the holes supporting the centre shaft. For that reason the top face and the angles at the sides are chosen as locating points. As in practice, we allow certain variations, it is obvious that we must allow some in the width of the top face of the knee. As the centre shaft must be parallel with the angles on the side of the knee, as well as with the top in order that the carriage may have adjustment along the top of the knee without cramping the centre shaft, we must locate sideways from one of the angles. This angle is called the "work" angle, because all measurements are taken from it. It is necessarily the fact that this angle is not the one on the side with the adjusting gib used in the carriage. This corresponding angle in the carriage is used to locate all holes in that part, so that when the carriage is assembled in place on the knee, the running parts go into place without trouble. In order to bring this within narrow limits the top of the knee and the angles are plated, that is, hand-scraped to special surface plates so that the desired results may be obtained. Should the scraping be left until after and the knee slid into the jig as from the planer, the variation due to scraping would cause considerable trouble. When

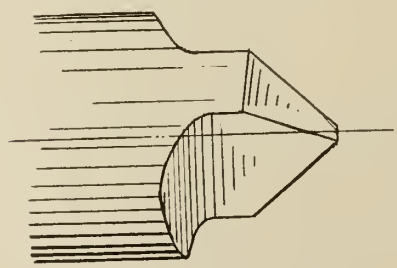

Fig. 5—The Spotting Tool.

we try to consider this done in both the case of the knee and the carriage, the error due to the after scraping would be doubled. Therefore we scrape the carriage or top bearing on the knee before placing in the jig.

Construction of Jig.

Fig. 2 shows that the jig is built up of three castings, the cover, which is made detachable being doweled and clamped to the jig proper by dowels in the upper face of the latter and by the clamps shown at the side, there being four of these clamps.

The jig proper is composed of two castings, one of which has the dovetailed slide on its inner surface for receiving the knee which is slid front end down into the box when the latter is in the position shown in Fig. 3. The slide is provided with a clamping gib which serves the double purpose of clamping the knee and forcing it over into the work angle. This gib is clamped by means of the three handles shown in the front of the jig. When the knee has been placed into the jig and clamped, the cover is put on and the clamps are brought into use. These clamps have the peculiar property of drawing the

Fig. 6—The Reamer.

hood down onto its seat and of clamping or binding themselves against loosening. This is accomplished by means of an eccentric bodied screw. Fig. 4 shows a section through one of the clamps, showing the screw and from which its working is plainly seen. In clamping the cover on, the turning of the handle causes the eccentric shoulder to draw the clamp toward its centre and the thread is at the same time drawing the clamp against the face of the boss, binding it in position.

The Use of Bushings in Jigs.

It is quite common practice to make for each hole to be drilled a double set of bushings, one set to guide the drill and the other to guide the reamer. This practice is not only expensive, but is liable to inaccuracy, due to wear of the bushing from constant removal. In incompetent hands trouble is liable to be caused by chips and grit becoming lodged between the bushings and their seats, throwing them out of line.

The above mentioned method is overcome by using but one set of bushings which are driven into their seats and are thus fixed in position, all wear being on the inside of them. The holes in these bushings are made equal in size to that of the hole or up to the size of the reamer.

The drill shown in Fig. 5 is used to start the hole and is called a spotting drill, the point is ground to the same angle as the twist drills that are used to drill the hole. The body of this spotting drill is made to fit the bushing, so that the hole is started right and if care is used in having the twist drill care-

fully ground and in good condition, no difficulty will be had in obtaining a straight hole. Where the hole is large and is drilled from the solid two or more sizes of drills are used. The drilled hole is then reamed out to size by the reamer shown in Fig. 6. This reamer is made with four flutes or lips, and is made to cut on the principle that a rose reamer acts. The lips are backed off as in the ordinary reamer, but all the cutting is done on the ends so that by grinding the ends, the reamer is kept sharp and in good condition. The trouble with the rose reamer is that the corners of the teeth become worn and the body of the reamer tears the hole leaving a rough hole much over size. The particular virtue of the reamer shown is that while its cutting is similar to that of the rose reamer—which is considered to be the best when in good working condition. when the corners of this reamer become dull the sharp lips then do the cutting, producing a nice, smooth hole, even under conditions due to carelessness. The formation of the flutes also allows plenty of chip space.

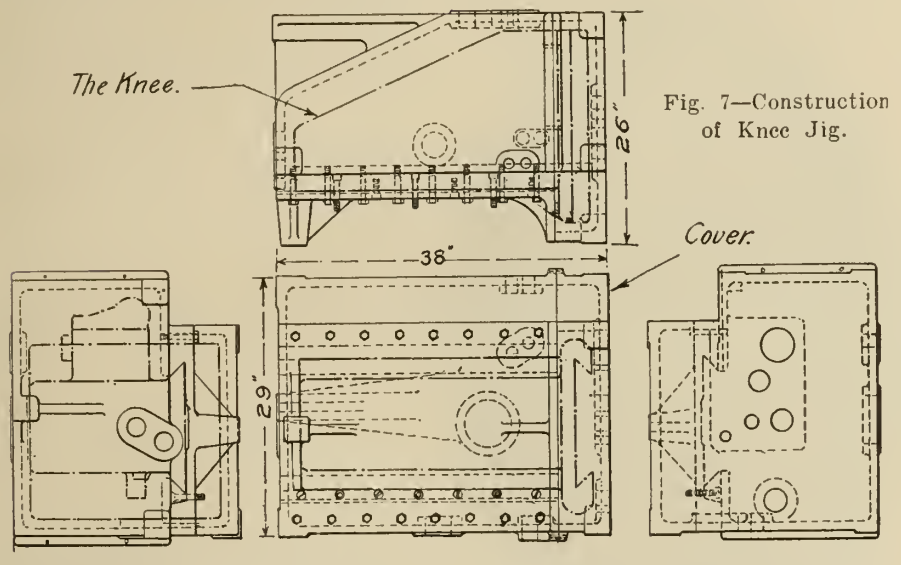

Fig. 7—Construction of Knee Jig.

The drilling in this case is all done under a radial drill and the jig placed in the several positions necessary to bring the bushings on the upper side.

The elevating shaft horn is not done in the jig in this particular case, but is performed at another setting. The hole is produced from the solid stock. A large hole is first drilled through as nearly in the proper position as can be assumed, the knee which is placed on an inclined plane is then readjusted so that the machine spindle is directly above the hole for the elevating screw. This hole is too long to allow a boring bar being used and the cut taken clear through because the bar would strike the inner wall of the knee. In order to bore this hole a telescoping bar was made.

The holes drilled in this jig a line within a half thousandth in the length of the knee and the time to drill all the holes was reduced to something like one-quarter of the time used to set one up on the boring machine, layout and bore the holes. The results in the latter case being anything but satisfactory as gears had to be turned into place, and extra work was placed on the assemblers due to poor alignments.

PRODUCER GAS POWER

Mr. L. G. Read, Consulting Engineer for the Colonial Engineering Co., Montreal, speaks of Cheap Power

The number of producer gas plants has very greatly increased in Canada. The city of Chatham is now erecting a municipal plant to be equipped entirely with gas engines and with an absolute guarantee that its street lighting plant shall cost only $25 per annum per lamp. Two years ago there were practically no gas engines in Canada. To-day there are probably twenty-five successful plants in operation and perhaps a hundred contracted for. I am putting in nine plants, now, myself in the province of Quebec alone.

The Lackawanna Steel Company, of Buffalo, has recently installed 40,000,-horse-power of gas engines, and this too within a stone's throw of Niagara Falls. United States Steel Co. is spending three millions of dollars substituting gas engines for steam engines. A single English gas engine firm built and shipped last year alone over eleven hundred gas engines. A gas engine with the highest priced fuel will produce a kilowatt hour (one and a half-horse-power) for a cost of only one cent.

The Peak Load and the Meter.

If the power commission will sell Niagara power at 2-10 of 1% per horse-power per hour through a meter, instead of by the peak load as they propose to do, said Mr. Read addressing the Stratford Board of Trade, it is the cheapest power that can be manufactured. This is equivalent to $17.50 per horse-power for 8,750 hours of power or 365 days of 24-hour power. With the present proposed arrangement, however, what you will really pay for and what you will really get is this:

Your load factor—that is your actual average horse-power consumption (public or domestic lighting or power) will likely not average over fifty per cent. of the peak (or say 2 500 horse-power). In this case you are paying just exactly twice $17.50 or $35 per annum per horse-power for the actual power you consume. If your average horse-power consumption is sixty per cent., then (based on $17.50 peak rate) you are actually paying $29; if seventy per cent., you are actually paying $25, and so on.

But, he said, electricity is a general utility and should be placed in the same class as other public utilities. The proposition of the commission was that "you simply pay according to the highest peak load in any twenty minutes during the month." This was the most dangerous feature in the whole subject and the one least understood by the public.

Producer Plant.

To the Toronto Council Mr. Read said he was prepared to hand over the construction of a producer gas plant to any one of four English engineering firms who would guarantee to produce electricity at 1c per kilowatt hour. He was also prepared to construct a steam plant which would produce power for Stratford at 2 cents per kilowatt hour. One cent per kilowatt hour for a producer gas plant meant $30 per kilowatt for 300 days of 10 hours each. This meant $20 per horse-power, the other $8 or $10 for interest and expense.

Long Service of Producer Plants.

Producer gas holds the record for continuous service. A producer gas engine will run as steadily as a steam engine. It is sufficiently safe to warrant its use. Of the engines failing in England last year there was 1 in 8 steam, and one in 12 gas. The reason so many gas engines failed in Canada was that every large machine shop in Canada was trying to make them whether it understood how to build them or not.

The Head of a Great Industry

Charles B. Frost, President of the Frost & Wood Company, Limited, Smith's Falls, Canada.

Many heads of large industries are unknown to the thousands with whom they do business, and to very few is it the privilege to see their face and receive the hearty handshake. Mr. Frost is respected and esteemed by all who know him and he has been called in business circles the premier of the captains of Canadian industry. He was born in Smith's Falls on August 26, 1840, and with his brother, the Hon. F. T. Frost, for one cannot be mentioned without the other, broad and deep foundations have been laid for a great industrial enterprise which finds its expression in the high chimneys and great buildings erected throughout the Dominion.

The business of which Mr. Frost is at present the honored head, was founded by his father, Ebenezer Frost, away back in 1839, the business at that time consisting of the manufacture of a few ploughs and stoves. Those were not the days when the proprietor of a shop sat in his glass-enclosed office and dictated letters into his phonograph and exercised a general supervision of the plant, etc. They were the days when the proprietor was foreman, moulder, office boy and everything else, all combined. Perseverance was an innate quality of the early pioneers and perseverance and hard work have developed that small and rudely equipped shop into the huge modern manufacturing establishment, which, while it is not the largest in size, is second to none in equipment and facilities for turning out the very highest grade of farm machinery.

The Firm "Frost & Wood."

About the year 1846, Ebenezer Frost formed a partnership with Alexander Wood, under the name of "Frost & Wood," and shortly after this the firm began branching out and adding new lines of manufactured goods. At that time there were no railroads to aid in the transportation of raw materials and finished products, so everything had to be teamed from "the front," or, speaking more definitely, from Brockville, or else brought up by boat. Rolling mills and blast furnaces were also unknown quantities in Canada, and all steel had to be imported from England.

In 1863 Ebenezer Frost died, and his two sons, Chas. B. and Francis T. Frost, with the late Alexander Wood as a partner, carried on the business. This partnership continued until 1885, when the Messrs. Frost took over the business, but still maintained the name of "Frost & Wood." Canada was growing very rapidly and the ever increasing demand for farm machinery necessitated a larger selling organization, so an office was opened in Montreal. That organization has grown from one branch office to a dozen, and covers every province in the Dominion, as well as many of the foreign countries.

Reorganization.

In 1899 the Messrs. Frost decided to form a joint stock company and with increased capital to push harder than ever the sale of Frost & Wood machines. There was a market for the goods which greatly exceeded the supply, and since 1899 the plant of the Frost & Wood Company, Limited, has been growing at a remarkable rate. Each year either new buildings were put up or substantial additions were made to the old. Warehouses were also erected in the different cities, in which branch offices are located, in which to store the finished product and have it ready for immediate shipment when called for.

CHARLES B. FROST.
President of the Frost & Wood Company, Limited.

Plant Lost by Fire.

The year 1906 was truly a disastrous one for this company, because on Feb. 8 of that year fire destroyed practically their entire manufacturing plant. It was a hard crack, but there is an old saying which states "that a person never knows what he can do until he has to do it." It certainly must have looked to these men like a hopeless task to try and replace their plant and still keep on the business. However, that is what they had to do and that is what they did. The smoke had not cleared away from the ruins when they had a gang of several hundred men cleaning away the debris and making preparations for a plant just twice the size of the one that had been destroyed. It took a lot of nerve and a lot of hard work, but the energetic officials of the company, backed by a progressive directorate and a loyal staff, not only put up a plant inside of one short year, but also supplied the demands of their customers and filled all orders for goods, with the single exception of binder orders. Temporary shops were improvised in old warehouses and mills in different parts of the town, and while manufacturing costs for 1906 were run up to an abnormal figure, still the organization of the company was held intact and ready to do business on a larger scale in the future.

This was a time when Mr. Frost's experience of almost fifty years stood his firm in good stead, because he knew every defect in the old plant and was able to avoid a repetition of such in the new buildings. To a stranger walking through the present plant, it appears that everything is just as nearly perfect as it can be. The different shops are light, airy and conveniently situated. They are now as nearly fireproof as automatic sprinkler systems, underwriters' fire pumps and a complete system of town hydrants can make them.

While Mr. Chas. B. Frost and his brother, the Honorable F. T. Frost, are both men well up in years, and have laid aside the responsibility of the minor details of the business, still every day finds them in their offices and just as interested in everything that is going on, as years ago, when their own shoulders had to carry the entire load.

W. S. Chase, sales manager of the National Acme Manufacturing Co., of Cleveland, Ohio, and W. C. Long, their Canadian traveler, were in Toronto during the last fortnight and paid Canadian Machinery a visit.

At The Noon Hour

Cheap Labor.

While an Irishman was gazing in the window of a Washington bookstore the following sign caught his eye: "Dicken's works all this week for only $4.00." "The divvle he does!" exclaimed Pat in disgust. "The dirty scab."

* * *

Considerate of Father.

"Johnnie," said a mother threateningly to a naughty son, "I am going to tell your father to whip you when he comes home to-night."

"Please don't do that, mother," said the lad penitently. "Dad's always so tired when he comes home!"—Philadelphia Inquirer.

* * *

Rich.

Blobbs—Why do they call Pittsburg the smoky city?

Slobbs—Because there are so many millionaires there who seem to have money to burn.—Philadelphia Record.

* * *

Needed, But Where?

"Did you see the discouraged-looking young fellow who was in a while ago trying to get a job?"

"Yes."

"That was J. Filber Browne, who read an essay at his college commencement on 'The World Needs Us.'"

* * *

A Drop in Copper.

"You look worried. What's the matter?"

"Oh, we're all upset at our house. There's been another drop in copper."

"But I thought you never speculated?"

"I don't. Our cook let the coffee pot fall on her foot, and she has had to go to the hospital."—Chicago Record-Herald.

* * *

Making a Fortune.

"With $100,000," said the man of expansive ideas, "I could make a fortune in Wall Street."

"Yes," rejoined the piker, "but whose fortune would you make?"—Washington Star.

* * *

Hope for Them.

A rich young man who was trying to learn to work had fallen in love with the daughter of his employer, but he found that his path was by no means clear of obstacles.

"You tell me your father objects to your marrying me," he said, in a crestfallen tone. "Is it because I am in his employ? I can leave it and go back to a life of idleness if he prefers."

"Oh, no, that isn't what he wants," said the object of his choice. "He says I may marry you just as soon as you're valuable enough to have your salary raised."—Youth's Companion.

* * *

A Good Time.

"Well, Pat," said the sympathetic employer, "did you go to your friend's funeral?"

"Did I go, is it sor?" returned Pat, enthusiastically. "Sure an' I did, sor, an' had the time o' me life sor. That wake wor a drame!"

* * *

Must Be Twins.

"See here, Pat," said his employer, "didn't you tell me that when you was out west the Indians scalped you. and now you have your hat off I see you have an extraordinary quantity of hair? You certainly told me so, didn't you, Pat?"

"Oi did, sor," answered Pat, "but Oi bear in moind now that it was me bruder, Mike. It's thot much we be aloike that Oi think Oi'm Moike an' Moike be me."—New York Times.

TORONTO'S MANUFACTURING DISTRICT.

A visit to the district north of the Dundas bridge, in the northwest of Toronto, presents to the eye of a visitor a scene of great industry and a walk around this section immediately adjacent to the C.P.R. and G.T.R. tracks presents a scene of great activity, which is bound to make Toronto a hub of industry. Here new factories are going up on almost every street. Some are nearing completion and others are either in course of erection or preparations are being made for construction, and more factories are promised for next spring. Cheap lands and room for expansion has attracted manufacturers to this district, until it now is a very bee-hive of industry. A brief survey of this district will prove interesting. It is situated along the G.T.R. and C.P.R. tracks and nearly every factory in the district has at least one spur line. The buildings are for the most part, large, well-built brick or reinforced concrete, the workshops are bright, spacious and airy and all are busy.

Beginning at the south we find the new plant of the Dominion Bridge Co., Ltd., a large building, 407x70 feet, now ready for construction work, the first of which will be for the Robert Simpson Co. Starting northward, we visit the new plant of the Chapman Double Ball Bearing Co., now complete in every particular; Robt. Watson Co., manufacturer of cough drops; the Toronto Laundry Machine Co., Ltd., makers of laundry machinery and supplies.

Old and New Plants.

Continuing northward we come to the Standard Meter Co., the plant of the Toronto Furnace & Crematory Co., Ltd., makers of furnaces, and the Johnston Oil Engine Co., Ltd., situated close to the Furnace & Crematory Co., R. Laidlaw, makers of frames, sashes, doors, moldings, etc.; the Sharples Separator Company, manufacturers of tubular cream separators; the Cyclone Woven Wire Fence Co., the Canada Malleable & Steel Range Co., Ltd., and the Bowman Gas Range Mfg. Co. Crossing the track eastward, we see the large plant of the Canada Foundry, general founders. Adjacent to the Canada Foundday is the Wilkinson plow foundry, and in this vicinity the Dominion Radiator Company has a large building in course of construction to keep pace with their increasing business. Near here, on Sterling avenue, the Fleer Co., of Philadelphia, will erect two large gum factories. South of this is Hancock Bros., manufacturers of sashes, doors, etc. The large plant of the Canadian Fairbanks-Morse Mfg. Co., Ltd., occupies several buildings, in which they manufacture gasoline, gas and oil engines, steam and power pumps. Following along is the Griffin Curled Hair Co., and on St. Helen's avenue is a fine block of new buildings. These include the plant of the Somerville Limited, manufacturers of plumbers' and steamfitters' brass supplies, and the King Radiator Co., which ran their first heat in the foundry in November 20th. Another row of factories consists of the new factory of T. A. Lytles for pickle manufacturing, Cowan's cocoa and chocolate works, Matthew's Bros., makers of moldings, frames, etc., and across the street is the General Brass Works, Ltd., a large new plant, 180x75 feet, where the manufacture of plumbers' and steamfitters' brass goods will be carried on.

Still in the distance, and outside these narrow limits we have outlined, arise numerous smokestacks which betoken more activity, and the large buildings spoke to us of numerous men busily employed, of machinery being built, strong and durable; of ideas being perfected and a name for Canada being built up on the good workmanship of the busy artisans. A few good sites are still open and Commissioner Thompson is in correspondence with a few large firms looking for Canadian sites, from which they will be better able to look after their Canadian customers.

CANADIAN MACHINERY
and Manufacturing News

A monthly newspaper devoted to machinery and manufacturing interests, mechanical and electrical trades, the foundry, technical progress, construction and improvement, and to all users of power developed from steam, gas, electricity, compressed air and water in Canada.

TECHNICAL NORMAL COLLEGE.

In providing for the establishment of technical schools at Quebec and Montreal, the Quebec Government has taken a practical step which commands general approval and which will bear good fruit before long. But there is an important point in this connection which should not be overlooked, and which is the desirability, sooner or later, of having an institution in the nature of a technical normal school or college for the training of teachers in technical work in order to meet the demand for such teachers.

Technical instruction is being introduced in the schools of several of the more progressive Ontario towns; it would be more generally introduced but for the lack of qualified instructors. Before long it will be necessary to have an institution for the training of teachers in technical work in order to meet the demand for such teachers.

It is proposed to establish a technical normal college in Hamilton and it is to be hoped that a provincial institution will be established. All Ontario teachers who desire to qualify as technical instructors will have to take the course prescribed, and the college will increase in importance and the scope of its work as the years go on and technical instruction is popularized.

TORONTO'S POWER SITUATION.

The ratepayers of Toronto will be asked on January 1st to vote $2,500,000 for a plant for the distribution of electrical power from Niagara Falls by a Government-built transmission line. Cheap power is a vital necessity for the industrial growth of Toronto and it is Commissioner Thompson's greatest problem to overcome when the question of power is mentioned by prospective new industries for that city.

According to the present plan the city can construct a distributing system which will provide for: Fifteen hundred street lights; power delivered to pumping station; lighting of public buildings; underground conductors in central area, three-quarters of a mile square, and main streets leading therefrom; supply of power to factories along railroad lines and all principal factory areas; supply of light and incidental power in suitable manner in all parts of the city where there is a reasonable demand; facilities for extension, namely—spare ducts in conduits, spare arms on pole lines, and spare floor space in sub-stations, the estimate being based on the receipts of say 12,000 horsepower, and these spaces being sufficient for an increase to say 20,000 horsepower.

CANADIAN FINANCIAL STABILITY.

That the financial stringency in the United States has not reached Canada to an appreciable extent is no doubt due to our system of banking which is entirely different from that in the country to the south of us. In the United States the revenues are locked up in the treasury vaults, while in Canada the revenues are deposited in the bank, just enough being reserved to cover saving bank deposits. As a result of our superior banking system, the currency is always ready for immediate use, the Canadian financial institutions are still issuing currency for the carrying on of legitimate industrial business. The Canadian banking system has shown its efficiency in withstanding the strain of the past two months, and United States financiers are calling for a new banking law modelled after the system in Canada.

At the present time Canadian banks have over $63,000,000 on "call" loans on Wall Street, and this cannot be secured except in the form of non-negotiable and easily counterfeited clearing house certificates. Canadian bankers have all along contended that it was a source of strength to the Canadian banking system to have from fifty to one hundred million in cash on loan in New York, subject to an immediate call, the effect of which would not be felt by Canadian industries.

The bankers were supposed to know their business and their expressed views were agreed to by many. Others,

however, contended that the money should not go out of the country to be used in gambling on Wall Street. Many lessons can be learned from the present financial flurry, one of them undoubtedly being the necessity of restricting the territory in which our banks can legally loan the money placed in their hands by Canadian depositors. Some peculiar incidents have happened in the United States, due to their financial stringency. The people of Detroit are depositing their money in Canadian banks and the Detroit Railway Company is paying its employes with Canadian currency. In another city the street railway paid out one payday, over $30,000 in nickles. In many places wages are being paid by cheque or clearing-house certificates. Some of the banks are also using clearing-house certificates in "cashing" cheques. With the help of the secretary of the treasury, this situation is being overcome and many banks report that they are ready to pay in currency as soon as New York sets the example.

QUEBEC BRIDGE DISASTER.

As the work of the Government Commission progresses, new developments arise and the cause of the disaster now appears to be due to modifications in the original design of the bridge made by the consulting engineer, Mr. Theodore Cooper. The testimony of the officers of the Phoenix Bridge Company was that Mr. Cooper changed the length of the original span from 1,600 to 1,800 feet, without making adequate changes in the support to compensate for the increased length.

"The fall of the bridge is to be laid directly to the change in the unit stresses as made by Mr. Cooper," said David Reaves, president of the Phoenix Bridge Co, in his sworn testimony, and he continued: "He made modifications in the unit stresses to be employed upon the various members, which very much increased them beyond any precedent, and by so doing placed the whole deisgn in a field outside the benefit of experience. Such high stresses had never before been used."

If this be true, the fault was in the design of the bridge of the bridge itself, not due to a flaw or defect in the material. When the Commission again interview Mr. Cooper, we anticipate a definite statement from them showing the cause of the disaster.

DOMINION BOILER ACT.

Pursuing the policy adopted by the engine and boiler section of the Canadian Manufacturers' Association on September 24th, at their meeting in Toronto, a second meeting of this section was held in Toronto on November 13th, and further steps were taken towards a uniform boiler construction act for all the Provinces of the Dominion, that would be satisfactory to the manufacturers and at the same time protect the consumer.

Canadian Machinery has noted the lack of uniformity in Provincial boiler regulations, and has been a warm advocate of a Dominion law to overcome the difficulties that must be met by both manufacturer and purchaser on account of the Provinces having their own acts. We are glad to see that the C.M.A. has taken up this matter and we hope to see in the near future a Dominion act that will meet the needs of all boiler manufacturers and purchasers.

The meeting was called at the instigation of the president of the Engine and Boiler Section of the C.M.A., Mr. F. E. Leonard, of London, and active steps are being taken to bring about the much-needed legislation. Since the meeting in September, the members have been collecting information regarding boiler construction and legislation in different countries, and a committee of experts, representing the largest boiler makers in Canada, will meet and frame a measure that will meet the requirements and interests of all localities. A united effort will then be made to secure a Dominion act to cover all stationary and portable boilers.

SAFE ELECTRIC WIRING.

The importance of entrusting electrical work to none but men who have a thorough knowledge of the business, and the dangers of allowing electric wiring to be done by incompetents is being impressed in Winnipeg. The City Electrician, in a report, says:

"While the legitimate contractors have lived up to the requirements as to safe wiring in a fairly satisfactory manner, this department is considerably handicapped by the fact that at present anyone may obtain a permit to install electric appliances, whether possessing any qualifications or not.

"Cities elsewhere are having the same difficulty in dealing with the matter, in consequence of which efforts are being made to regulate the matter by licensing master electricians and by the institution of a board of examiners."

Canadian Machinery has reviewed the question of electric wiring in past issues and pointed out the results of incompetent work. It seems to us that such important work as wiring, which has been the cause of so many fires, attended with loss of life, ought to be regulated by examinations of qualifications of the electricians. The insurance companies recognize this fact and very stringent regulations are enforced in this work. The city councils should unite with them to secure satisfactory workmanship.

MAKE GOOD USE OF OPPORTUNITIES.

A young man starts on his apprenticeship looking forward in anticipation to the opportunities that will open up when his long term of apprenticeship is over. Yet it is not the opportunity that makes a man of him, it is the use he makes of it and he may be ever so faithful and industrious, but if he has not the intelligence to make good use of his opportunities he is not fit for promotion.

Every young man cannot have a college course, but every young apprentice can give one night a week for study if he wishes to make a success in life. Recreation is essential, but to spend night after night in amusement is neglecting a great opportunity open to every young man. He will sometime be thankful for the time spent in study. There is some satisfaction in "knowing how," and knowledge is not burdensome. The Government may establish technical and industrial schools in every city and town, but it rests with the young man to apply himself. Thus preparing himself by a few hours' study each week, he will be better able to make use of his opportunities when they present themselves to him. If an apprentice is promoted and called upon to make a drawing or design a machine, would it not be a great satisfaction to know how to do it. Theoretical combined with practical knowledge is a great benefit to a man. To be able to make the drawing, to be able to design the machine, is to make use of his opportunities and the knowledge that he can do the work he is called upon to do adds greatly to a man's self-respect. To be able to make use of the opportunities is success. Success is not gauged by wealth, but by the honesty, faithfulness and intelligence which command the respect of others.

The Art of Making Machinists' Tools

Practical and Scientific Methods of Manufacturing Steel into Tools

By H. Holford

Connected with the machinist's trade is a wide range of fine and complicated tools, among them being lathe and planer tools, milling cutters, taps, dies, reamers, etc., and the toolsmith in a large shop who can forge, harden and temper these tools satisfactorily will have a great many friends among the machinists, but should the toolsmith be otherwise, there is nothing that tries the temper and patience so much as to have a number of machinists continually around the fire and each one making a complaint that the tool would not do this, and it would not do that, etc.

When making lathe and planer tools, there is no definite rule to go by "as to the shape," with the exception of a few standard or ordinary tools, as shown in Figures 1 to 4, as the machinist has so many jobs of a different nature that he requires a tool of a special shape to suit the work, which he explains to the toolsmith or gives him a drawing of it, and sometimes a pattern of it made from wood. Steel of 1 per cent. or 100-point carbon is best for making

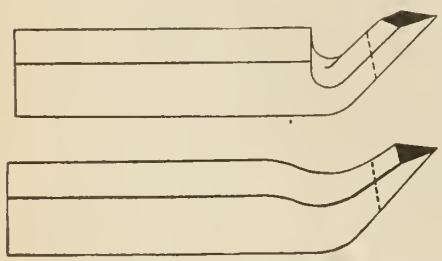

Fig. 1—Two Ways of Forging a Diamond-point Lathe Tool.

lathe and planer tools, as these tools do their work by steady pressure. But nevertheless they must be properly forged, hardened and tempered in order to stand the great strain that is continually bearing against them, and also to hold a good cutting edge in order to save time, and do work of a very exact and skilful nature, especially in the finishing stage.

Lathe tools of a flat surface, such as bent cutting-off tools and side tools, must be forged to shape and the offset put in before the last hammering is done. When making cutting-off tools and other tools of a similar nature, always give plenty of clearance, as illustrated in Fig. 2, which shows the cutting edge a little wider than (b), also wider than (c) as shown in front view of the same figure, and bear in mind when forging the tool to leave it a little wider at the cutting edge than the exact width, as the hammering on the flat surface after the offset is put in, will bring the cutting edge to the right width. To more fully explain, let us suppose the cutting edge of the tool is to be ¼ of an inch in width, but in order to refine and pack the steel, we will have the cutting edge 5-16 of an inch wide before undertaking to hammer on the flat surface. If the hammering does not flatten the steel to exactly the right size and so leave the cutting edge a trifle wider, so much the better, as the tool will have a little stock for grinding.

All lathe and planer tools for ordinary work should be quenched or hardened about one inch back and according to the cutting edge, as illustrated by dotted lines in Figures 1 to 4, and tempered to a dark straw or copper color. But should the tools have to cut very hard cast iron or other very hard material, harden and draw no temper. Should the tool still fail to cut the metal, use equal parts of powdered cyanide of potassium and prussiate of potash. To use this compound heat the tool as hot as if it was to be hardened, then place the heated cutting edge of the tools into the powder, reheat again to a proper hardening heat and plunge into the hardening bath and cool off entirely.

When hardening large tools, such as square corrugating tools, and which have very fine teeth in the cutting end, make sure when heating that the centre of the cutting face is as hot as the outside or corners. And never heat carelessly or too fast, so that the corners will be at a white heat, while the centre is barely red. But heat slowly and very evenly, until the whole face of the cutting end is just hot enough to harden, then plunge into the hardening bath and cool off entirely. Draw no temper.

Heat slowly and evenly until the whole face of the cutting end is just hot enough to harden, then plunge in the hardening bath and cool off. Ordinary corrugating tools require no temper drawn.

Air-Hardening Steels for Lathe and Plainer Tools.

Cast steel for lathe and planer tools is to a certain extent done away with in large shops by the use of air or self-hardening steels. A certain amount of this steel is manufactured in sizes so that no forging of tools is required, and by the use of a patent tool-holder (made especially for certain sizes of the steel) is superior to a hand forged tool in some respects. But the toolsmith has an important work to do connected with air-hardening steel, as he is called upon to cut it off in lengths and harden it, besides. As there is a limit to the sizes that are manufactured for immediate use, the steel must be forged to the shape of the tool, while the forging and hardening of air-hardening steel is somewhat of a different nature to cast tool steel. Air-hardening steel is not, as a rule, used for anything but for roughing lathe and planer tools, it being too hard to make into any tool which is to do its work by the use of a hammer and also to make into any expensive tool such as milling cutters, as on account of its extreme hardness it cannot be machined or worked satisfactorily. There are several makes and brands of air-hardening steel, but some of the leading makes may be mentioned, as Sanderson's, Jessop's, Novo, Mushet

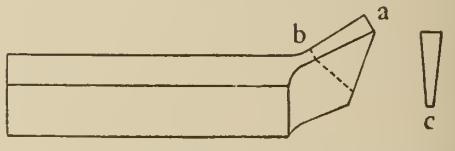

Fig. 2—The Left-hand Bent Cutting-off Tool.

and Blue Chip. When forging these brands into tools, do not heat the steel above a bright yellow, especially Mushet or Sanderson's, but the steel must be heated evenly clear through the bar, and unless the tool is to be of a fine nature do the forging under the steam hammer and sledge. The forging should be done as quickly as possible, while the heat is in the steel, and never attempt to bend or crook the steel when at a low heat, as it will be apt to crack or break in two, so be careful to have the steel at least at a deep red heat when it is to be bent.

When any new brand comes into the shop, be careful to look at the directions on the bar, as some brands are hardened a little different from others. For example, the cutting edge of a tool made from Blue Chips is hardened by being heated to a white heat until it commenced to melt, when small bubbles or blisters will form on the steel, then

* Extract from the 20th Century Toolsmith and Steelworker, by H. Holford, copyrighted and published by permission of Frederick J. Drake & Co., 350 Wabash avenue, Chicago.

it is placed in a blast of cold air. To harden Mushet steel, heat to a deep yellow and cool off in a blast of cold air ; Sanderson's and Jessop's after the same process. Novo steel is hardened by heating it to a white heat, then cooled off in a blast of cold air, or may be quenched in oil.

When hardening steel with a blast of cold air, have the pipe or nozzle (which

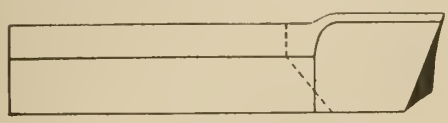

Fig. 3—The Left-hand Side Tool.

conveys the air) as close to the fire as possible, and when cooling off the tool, have same arranged to hold the point or cutting edge directly in front of the blast. If this is not done the tool is apt to become turned to one side by the force of the blast. Also bear in mind if the steel is heated to a melting heat, as Blue Chip, be careful not to put the blast on too strong at first or it will blow the point off the tool. Instead, put on the blast light and gradual until the steel begins to cool a little. Then turn on the blast to its full capacity and keep on the tool until it is perfectly cold.

A great deal is to be learnt in working air-hardening steel in order to get the best results. But for the beginner who has had no experience, follow up the directions given by the manufacturer. Should the directions fail to give good results, do some experimenting. For illustration, Novo brand of steel will give good results if heated to a white heat, then plunged into oil or boiling water, while Blue Chip will sometimes give better results if (after being heated to a melting point and cooled off in a blast of cold air) it is heated to a very low black red heat and allowed to cool of its own accord. Yet there are other brands of steel that are hardened by heating to a light yellow heat, then placed in a cool place and allowed to cool slowly of its own accord.

Never allow Mushet steel to come in contact with water or it will crack, although no visible heat can be seen in the steel. Figure 5 illustrates a heavy roughing tool, made from air-hardening steel, for turning locomotive tires, car axles, etc. Dotted line at (a) indicates how far back from the cutting edge, as (b), the steel is to be heated when hardening. All roughing tools are made after the same shape. Bear in mind when forging air-hardening steel, never try to forge it below a low cherry red, and if at any time it is necessary to cut a bar into lengths, do not try to cut it cold, as it must be heated.

How to Anneal Air-Hardening Steel.

Sometimes, although seldom, the toolsmith is called upon to anneal air-hardening steel, so that it may be turned and planed. This class of steel is very difficult to anneal on account of its extreme hardness. It must not be packed directly in slacked lime or ashes, as cast tool steel, as it will cool off too quickly. To anneal air-hardening steel, use an air-tight, heavy iron box, place the steel inside the box, then heat altogether to a deep red heat, then pack the box deep into slacked lime or ashes. If an iron box cannot be obtained, use a heavy iron pipe or band large enough to accommodate the steel, without having the steel project out through the end. Also have two heavy flat iron plates large enough to cover the end of the pipe. Place the steel in the pipe and heat the pipe, likewise the plates, as formerly mentioned, then pack the pipe into the lime in an upright position, having one of the plates directly under the pipe, the other on top, which will keep the steel from coming in contact with the lime. By following this method the steel will keep hot a very long time, and thus give good results. To anneal a piece of 1-inch square air-hardening steel will require from twelve to fifteen hours' time.

Milling Cutters.

These tools are very valuable to the machinist's trade, and the making of them requires great skill, valuable time and good steel, which makes them very expensive tools. If they are not properly forged and hardened there is a great loss.

When forging a blank for a milling cutter, (steel about 90 point carbon is best) be sure and leave the blank a little larger every way than the exact size of the milling cutter when finished,

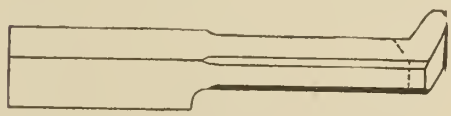

Fig. 4—The Inside Boring Tool.

as a machinist always prefers a little extra stock, which enables him to machine the tool with greater ease and less caution than if forged to the exact size of the tool. When forging a milling cutter, heat the steel evenly to a good yellow, but do not heat too fast or the outside or corners will be at a white heat while the inside is barely red, and by unevenly heating will cause strains which will produce a tendency to crack when hardening the milling cutter.

If the milling cutter is large, forge it to shape under the steam hammer, being careful to forge it evenly from all sides alike, and so work the steel clear through, but as it becomes finished, reduce the heat. Tools such as milling cutters, which are either round or almost of an equal size, cannot be refined, as the steel will remain at its natural state, consequently it is not desirable to finish at quite so low a heat as those of a flat surface. But if the milling cutter is very thin and flat then the

Fig. 5—Heavy Roughing Tool.

steel may be refined by using a flatter on the flat surface while at a low heat.

Annealing Milling Cutter.

After forging the milling cutter, it must be annealed, which operation must not be neglected, as the whole blank must be heated again slow and evenly to a blood red, (never exceeding a cherry red) then packed deep into slacked lime, allowing it to remain there until cold. Have the annealing box large enough so that it will contain plenty of lime to keep the heated steel away from the air. If there have been any slight strains left in the steel by forging, the annealing will take them out and make the steel soft so that it can be worked with ease by the machinist.

The hardening of a milling cutter after it has been machined to shape, is the process that must not be overlooked, as in the hardening the toolsmith must either succeed or spoil the tool. The milling cutter must be hardened properly without cracking, so that when put into use it will do a great amount of cutting by holding a good cutting edge, and so it is necessary that the toolsmith use great care when heating for hardening. If there is no heating furnace in the shop, and the milling cutter is to be heated for hardening in the coal or open fire, too much care cannot be used.

When heating to harden in the open fire, have the coal well charred and the fire plenty large enough. The top of the fire should be perfectly flat and the whole surface a perfectly and very evenly heated mass, place the cutter (if after the shape as (b), Figure 6) flatway on the top or surface of the fire, now heat very slowly and evenly and turning it over occasionally until it is heated to a very even, low cherry red, or just enough to harden, then plunge it into the hardening bath edgeways from a vertical position, allowing it to remain deep in the bath until quite cold, then dry off and polish bright.

Tempering Milling Cutter.

To temper the milling cutter, take two round bars of iron about two feet long and just large enough to go through the hole in the centre of the milling cutter, put one end of each iron into the fire and heat to a white heat to about two inches back from the end or according to the thickness of the tool. Now take one of the irons (leaving the other in the fire) and place the heated end directly in the centre of the milling cutter, holding there until the temper in the teeth has drawn to a dark straw color. If the iron cools to a low heat before the temper is drawn to the exact color, use the other iron which was left in the fire to finish drawing the temper, then cool off. Should the milling cutter have very heavy teeth, or if it is to cut very hard metal, it will not be necessary to draw any temper.

If the milling cutter be to the shape and size, say 4 inches long and 2½ inches in diameter (or larger sizes), as a, Fig. 6, a good way to heat for hardening in the open fire is to have a heavy iron pipe about 6 inches long and plenty large enough for the cutter to go inside. A pipe about 1 inch wider than the diameter of the milling cutter will be about right. Place the pipe in the fire and building the coal on top of it, but do not build the fire over either end of the pipe. Instead leave the ends of the pipe open and do not allow the coal to get inside the pipe. By this method an opening is left clear through the fire. Heat the pipe to a bright cherry red the whole length, insert the milling cutter and heat it to the necessary heat to harden, then plunge into the hardening bath from a vertical position. But when heating to harden a milling cutter which has very fine teeth after this method, be very careful not to bruise the fine cutting edges of the teeth against the pipe. It is better to have something arranged to hold the milling cutter up from the pipe. An iron bar placed through the centre of the cutter with a bearing under each end, will keep the cutter from coming in contact with the pipe.

The Use of Asbestos and Clay, When Hardening Milling Cutters and Other Tools.

Very often a milling cutter is made with a thread through the centre of the tool which must be kept soft, while the outside or teeth are hardened, and the way this process is accomplished is by the use of asbestos, which is packed well into the inside or thread, but make sure that the outside ends of the thread are well padded over without allowing the asbestos to come in contact with the cutting edges of the teeth of the milling cutter. The asbestos is kept in place while hardening by the use of fine pliable wire, wrapped around the tool. After the hardening has been done and the asbestos taken from the inside the

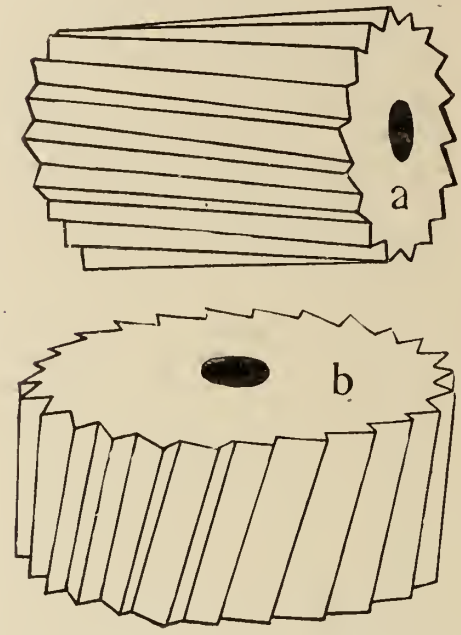

Fig. 6—Plain or Ordinary Milling Cutters.

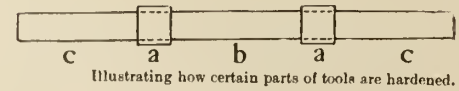
thread will be quite soft. The reason the thread has remained soft while the teeth are hardened is because the water could not come in contact with the thread when being quenched, on account of the presence of the asbestos.

I have saved a great many delicate and expensive milling cutters from cracking when hardening, by the use of asbestos. Take, for example an angle end milling cutter. That is made with a thin or delicate part extended from the main body of the tool. Now, although the tool may be very evenly heated and properly hardened, it is still very liable to crack, and in some cases the thin or extended part will crack off in a solid ring. To stop a milling cutter of this kind from cracking, fill the hollow in the end with asbestos, being careful not to cover any of the cutting edges of the teeth and hold the asbestos in place by the use of fine



Illustrating how certain parts of tools are hardened.

Fig. 7—Hardening Certain Parts.

wire, while hardening. The reason the tool will not crack is, when quenching to harden only the teeth side comes in contact with the water which hardens, while the other side is kept soft as the asbestos keeps the water from coming in contact with the hot steel.

Another example: Take a piece of steel 3 inches long and 1 inch thick, now an inch on each end is to be hardened, while the remaining inch in the centre is to be kept soft, and to accomplish this process, wrap the centre well with asbestos, keeping it in place by winding some fine wire around it, or instead of using asbestos, wrap the steel around with clay, keeping it in place by the use of a thin piece of sheet metal wound around it, then heat to harden and the results will be as formerly explained.

Hardening Hollow Tools.

When hardening milling cutters as a, Fig. 6, spring threading dies or any similar tool, always quench them from a vertical or upright position, which will allow the steam and water to come up through the tool and cause the steel to be hardened more evenly. Should the tool be quenched from a horizontal position it will be impossible for the steam to escape, and which will keep the water from coming in contact with the hot steel. Thus, when the water is held back by the steam there is a tendency for soft spots in the tool.

As a rule, steel workers never pay any attention to the steam when hardening, which is a great mistake, as many tools are partially, if not altogether, spoiled (more especially if the tools are of a delicate nature) by the great amount of steam which rises as soon as the hot steel come in contact with the water. Delicate or fine tools of a hollow nature will sometimes warp or even crack, caused by steam and improper methods of quenching.

When hardening a spring threading die, it is not necessary to harden the whole tool, but just far enough back from the thread to allow the temper to be drawn with safety. To draw the temper, after being hardened as just mentioned, hold the end or thread part of the tool above the fire and draw the temper very slowly and evenly (by keeping the tool turned around) to a dark straw color.

The Hardening and Tempering of Hob Taps, Stay Bolt Taps and Similar Tools.

In forging, annealing and hardening of long, slender tools, such as hob taps, stay bolt taps, etc., too much care cannot be exercised, although, as a rule, these tools do not have to be forged, as the steel is generally obtained from the manufacturer the right size to allow it to be machined into the tool. However, the steel should be well and evenly annealed, should it come direct from the manufacturer or should it be forged by the toolsmith.

In annealing as well as hardening long, slender tools, they must be carefully handled when the tool is heated the whole length of itself or it will warp easily, also pack the tool very carefully when annealing so that it will have an equal bearing.

When hardening get the tool to a very even heat, enough to harden the whole length of the thread, and when quenching dip deep in the centre of the hardening bath from a perfectly upright position, allowing it to remain in the bath until perfectly cold. Bear in mind that when quenching a long slender tool, any variation from a perfectly upright position will have a tendency to warp the tool. When hardening do not harden the shank, as all that is required to be hardened is the cutting teeth or thread.

To draw the temper, polish bright the grooves in the thread from end to end. have a couple of heavy wrought iron pipes or bands. Heat both in the fire to almost a white heat, then remove one from the fire and put it in a convenient place, place the tap in the heated pipe and draw the tap back and forth to insure a very even temper from end to end. If one pipe is not sufficient to draw the temper, replace with the hot pipe that is in the fire, then cool off the tool. For all kinds of taps draw the temper to a dark straw color. Be sure when drawing the temper not to use too small a pipe, or the extreme fine points of the thread will draw too quickly. For all ordinary taps use a pipe about five inches long and 3 inches inside diameter, while the thickness of the pipe should not be less than ¼ an inch or it will cool off too quickly.

Sometimes when hardening a long slender tool only a certain part of it is to be hardened. For example, supposing we have a long slender tool 18 inches long and 1 inch thick. Now 6 inches in the centre is to be hardened, while 6 inches at each end is to be kept soft. In a case of this kind take an iron pipe 7 inches long and 2 inches inside diameter, build the pipe into the fire a little above the surface of the forge, and heat the pipe evenly all around and from end to end. Now place the tool through the pipe, having the part which is to to be hardened directly in the heated pipe, while the ends which are to be left unhardened will project from each end of the pipe, which will prevent them from becoming hot enough to harden. To keep the tool from warping or bending (while being heated) place something under each end close to the pipe to form a bearing and also to keep the tool in the centre of the pipe. If the tool is to be hardened to a very exact length wrap with asbestos at the ends of the part which is to be hardened, as the asbestos will prevent the steel from becoming hardened while being quenched. To illustrate this more clearly, a a, Fig. 7, represents the asbestos, b the part of the tool which is to be hardened, and c, c the unhardened ends.

Heating Furnaces.

In large shops and factories where tools are made in great quantities, furnaces are used to heat steel, but principally for hardening purposes, and in a great many respects a furnace is superior to an open fire, as steel can be heated in a furnace very evenly and with less danger of it becoming overheated than if heated in an open fire. Tools of a long slender shape, such as stay bolt taps, and tools of a very wide and flat surface such as milling cutters, are best heated in a furnace. Different kinds of fuel are used for heating furnaces.

The principal ones used are gas and oil. Gas, however, is preferred, as the furnace can be very readily regulated in order to heat the steel to any degree of temperature. There are many different makes of furnaces and different methods of operating them.

Heated Lead for Hardening Purposes.

The lead bath is extensively used for heating steel when hardening, and has many advantages that a furnace does not possess, as in the lead bath certain parts of tools may be heated in order to harden with ease, and the temper drawn in many ways which could not be accomplished with a furnace.

When heating steel in lead, be sure to use a chemically pure lead, containing as little sulphur as possible. Sometimes when heating in lead there is danger of it sticking to the tool when hardening, but to overcome this difficulty make use of the following compound: Take a pound of powdered cyanide and dissolve it in a gallon of boiling water afterwards allowing it to cool. Now dip the articles to be hardened in the liquid, remove them and allow to dry before placing them in the lead. The liquid when allowed to dry on the tools will form a moisture on the tools when in the heated lead and prevent the lead from sticking. If lead is allowed to stick to the tool while hardening it will cause soft spots where the lead remains. When heating tools with fine projections, have a fine brush and clean off the tool should any lead happen to stick to it.

To obtain the best results when heating in lead keep the lead stirred up, as it will always naturally be the hottest at the bottom.

A lead bath is preferred to an ordinary heating furnace, as steel heated in lead will not raise a scale; also if the lead is heated to the proper degree it will be impossible to overheat the steel, consequently the steel will be very evenly heated. Should there be a great many small tools to harden at once, place them in a heavy wire basket or sieve and lower into the lead; after being heated they may be all quenched together.

AN IMMENSE WHEEL.

A pair of the largest wheels ever built in Canada have just been completed in the works of the Laurie Engine and Machine Co., Limited, Montreal. These are for the Canada Tin Plate and Sheet Steel Co., of Morrisburg, and are immense pieces of work. Some idea of the magnitude of these large wheels can be obtained from a description of them. They are 30 feet pitch diameter, 30 feet 3 inches outside diameter, 48½ inches face and weigh, including shaft. 180,000 pounds.

Each wheel is grooved for twenty-two 1¾ inch ropes. The rim is made up of twelve sections supported by twelve arms and two hub plates. The securing of these pieces together necessitated the use of nearly 200 bolts. In order to secure the accurate fitting of parts, jigs and gauges were made and all parts were accurately machined and fitted to these before being assembled.

The hubs were pressed and keyed to the shaft, after which the shaft was centred in a large lathe. On account of the weight, supports were used at either end to keep the wheel on true centre in the lathe. The inside of each hub plate was then forced to gauge for the arms so that when the arms were inserted they were exactly perpendicular to the shaft centre. The arms were then placed in position each one being accurately spaced by means of special gauges. The rim was put on last and when all the parts were assembled the bolt holes were reamed and fitted with turned steel bolts, a rigid construction being the result. The finishing operation was the turning of the grooves for the ropes. This was done without removing the wheel from the assembled position in the lathe so that a finished wheel, concentric with the shaft and running perfectly true was secured.

H. L. Hibbard, electrical expert to the Bureau of Construction and Repair, U.S. Navy Department, has resigned that position, to enter the employ of the Cutler-Hammer Mfg. Co., of Milwaukee, makers of electric controlling devices.

A New Departure in Lubrication

Mr. Edward G. Atcheson, Niagara Falls, N. Y., in a Paper Before New York Electrical Society, October 23, 1907, Describes his Latest Achievement

Mr. Acheson's address was a revelation. He told of persistency, of determination, of the careful workings of an inventive mind in search of the secrets of nature. He opened his remarks with a reference to his discovery in 1901 of the effects of tannin on clay, his effort at that time being to make common clay plastic and of greater tenure of strength. His words carried his audience back to the time when the Egyptians used straw in making bricks, telling that he conceived the use of the stubble was not for any benefits derived from the fibres, but from the extract. The use of this extract of straw or tannin, he found, increased the strength of the clay very much, some times as high as 300 per cent., but he also observed that clay treated with tannin remained suspended in water indefinitely. For this there is no known explanation. It is simply an "effect," and, as it was discovered by Mr. Acheson, it will probably be called the "Acheson effect."

Perhaps its great importance did not at first appear, but along in 1906 Mr. Acheson discovered a method for making a fine unctuous graphite of the refuse matter, the culm piles of the anthracite coal regions. For years he had been in search of a suitable material from which to make a graphite applicable to lubrication. Every part of Europe and America was canvassed, but right at home, in the great culm piles of Pennsylvania, he found it, and because of this discovery the world is to benefit, the unctuous graphite made at Niagara being almost chemically pure, or over 90 per cent. in purity.

Discovery of the "Effect."

After Mr. Acheson had made this unctuous graphite the thought occurred to him that tannin might have the same effect on it that he had found it to have on clay. He tried it with successful results, the graphite being reduced to an extremely fine condition, believed to be molecular. It remained suspended indefinitely in water and will pass through the finest filter paper. Mr. Acheson related how he had found the "effect" was also produced by the extract of sumac oak bark, spruce bark, and even tea leaves, and that not only was the effect produced on graphite and clay, but apparently on all non-metallic amorphous bodies generally, having been secured with silica, alumina, lampblack and even his new product, siloxicon. He considered the wide distribution of these re-agents, admitting it is difficult to appreciate or realize the important part that this "effect" may have in nature's economy.

Mr. Acheson became impressively interesting when he told that it was this "effect" that prepared the clay for the potter's use, and that he considered the effect on amphorous bodies to be one of deflocculation. "As found in nature," he said, "amorphous bodies are in what is termed a flocculated state; namely, the molecules of the body are grouped together in masses of appreciable size, and to deflocculate them is to separate them into the molecular condition," when they assume the colloidal state. He admitted that in assuming this state the deflocculated body apparently sets at naught the laws of gravitation, for in this "collodial" state deflocculated graphite, weighing approximately two and one-quarter times more than the water in which it is suspended, will remain indefinitely in that suspension without any noticeable disposition to settle. Waters of rivers, lakes and deep wells have so many impurities that they are unsuitable for the production of this state, but he had found the addition of a little ammonia corrected the ordinary water.

Aquadag is the name Mr. Acheson has given to the new lubricant made by suspending graphite in the water, while Oildag is the name he has selected for the lubricant made by suspending graphite in oil. This deflocculated graphite in water has been found to make an excellent lubricant for light work, the graphite preventing rust of any of the parts, while for heavier work the Oildag lubricant has been found ideal, he said. He went on to tell how both Professor C. H. Benjamin, dean of the engineering schools of Purdue University, and himself had made exhaustive tests, each one of which demonstrated the wonderful efficiency of these new lubricants.

A Practical Test.

Possibly the most satisfying test of all was that made at the works of the General Electric Company at Schenectady, N.Y., under the supervision of W. L. R. Emmett. These tests were not made to include the co-efficient of friction, but of the temperature and the surface speed of the shafts in the bearing. The shaft measured seven and a half inches in diameter, resting in a bearing twenty-one inches in length. The test covered both forced lubrication and oil ring lubrication. Not a great deal of advantage was shown in the case of the forced feed lubrication, the presence of the graphite holding down the temperatures but a very little. In the test on the oil ring feed, however, very pronounced advantages were shown in favor of the graphite.

It is astonishing to think that the graphite content as used in these tests was 0.35 of one per cent. of the weight of the oil, but the tests showed that with the same pressure and temperature " a shaft can be run from 30 to 100 per cent. faster with the graphite in the oil than with the plain oil."

The supported statements of the address will bring happiness to automobilists, for Mr. Acheson stated he had run a heavy car lubricated with Oildag over 4,000 miles without the necessity of cleaning the spark plugs, and, what is still more remarkable, without the necessity of grinding the valves, while materially reducing the consumption of oil. The results would indicate that the use of Oildag in the gas engine will eliminate the pitting of the valve seats.

The surfaces produced on the valve seats are remarkable, being much finer than is possible of attainment by any mechanical finishing, the graphite being incorporated in the body of the metal. The compression is so perfect and remains so that it usually starts on the compression after standing over night.

The address closed with the intimation that the use of this new and modern lubricant will greatly reduce the consumption of lubricating oils, and the audience realized another leg is about to be knocked from under the Standard Oil Company, the major part of whose business has been the sale of lubricanting oils, but the tests made give assurances that the oil consumption will be reduced over 20 per cent., which will be a tremendous volume considering the immense quantity of lubricating oils used annually.

"I will lubricate the bearings of the world," is the slogan adopted by Mr. Acheson.

Practical Questions and Answers

Ques.—I have a planer on which I wish to do some milling. What speed should the planer be run, also, what speed should I run the milling cutters?

Ans.—The speed of the cutter depends on the work to be done and on the shape and width of the cutters. No standard rule has yet been arrived at for the varied conditions that arise, the different amounts of stock to be removed and the rigidity of the planer. It has been found good practice to give the cutter a lineal velocity of 40 to 50 feet per minute for cast iron and a feed of two to three hundredths of an inch to one revolution of the cutter; a velocity of 30 feet per minute for wrought iron or soft steel and a feed of from one to two hundredths to each revolution of the cutter. These speeds, however, may be increased or decreased to suit the particular class of work to be machined.

Ques.—I wish to case-harden machinery steel. Will you tell me the process followed to case-harden them to a depth of say 1-64 or 1-32 of an inch?

Ans.—Cyanide of potassium is sometimes used, but as it is very poisonous great care should be exercised in handling it. The work to be case-hardened is put in the case-hardening box and heated in a furnace. When the work becomes a cherry red sprinkle with cyanide and after fifteen minutes sprinkle again and dump the steel into cold water. A better method and one that will give more satisfactory results in hardening the steel is to pack the steel in raw bone and wood charcoal in parts one to five and heat in the furnace for about three to twelve hours after it becomes a bright red. Let the box cool and then reheat the steel, without the bone and charcoal, to a cherry red and dump in cold water. This second heating will increase the depth of the hardening. Mere hardening of the thin outer surface will do very little if any good.

Ques.—Why is oil used in turning and drilling wrought iron and steel and is not used when machining cast iron?

Ans.—The use of oil and compounds in machine shops is the result of experience which shows how different materials can be worked to the best advantage. These prevent the overheating of the tools and so facilitate the cutting. The best machine shops practice is to use water when machining wrought iron or malleable iron and nothing on steel or cast iron. Oil is sometimes used for turning and drilling wrought iron or steel, but the above is the general practice now adopted.

Ques.—What is the meaning of lead and lap in a slide valve engine?

Ans.—The amount of opening measured in a fraction of an inch, which allows steam to enter at the instant the crank is on dead centre is called the "lead." This amount varies from almost nothing up to $\frac{3}{8}$ of an inch or even more. Slow speed stationary engines may have from 1-64 to 1-16 of an inch lead. When the valve is in this central position, the distance the valve overlaps the steam edge of the port is called the outside lap or steam lap. The distance the inner or exhaust edge of the valve laps over the exhaust edge of the port is called the inside or exhaust lap. The two terms inside and outside lap are often confusing, especially in valves where the steam is admitted by the inside and exhausted by the outside edges. The steam lap is much larger than the exhaust lap, which is sometimes zero and is often made negative. In this latter case the distance between the edge of the valve and the edge of the port is sometimes called inside or exhaust clearance.

Ques.—How do you figure the gears on a lathe for cutting threads?

Ans.—In a simple geared lathe where the stud and the spindle run at the same speed, select any gear for the screw, multiplying the number of teeth by the number of threads per inch in the lead screw and divide the result by the number of threads you wish to cut. This will give you the number of teeth in the gear for the stud. If this number is a fraction or you do not possess a gear with that number of teeth, try a different gear on the screw. In a compound lathe first select at random all the driving gears, multiply the number of their teeth together and this product by the number of threads you wish to cut. Second select at random all the driven gears except one, multiply the numbers of their teeth together and this product by the number of threads per inch in the lead screw. Third, divide the first result by the second and you will get the number of teeth in the remaining driven gear. Sometimes the gears on the compounding stud are fast together, but there is usually a definite relation between the gears. The driver has usually half the number of teeth as the driven gear and this can be allowed for by multiplying the number of threads in the lead screw and using this amount in the calculation. When the stud on which the first is placed revolves at half the revolutions of the lead spindle allowance is made by doubling the number of threads on the lead screw. If both these conditions are present, multiply the number of threads on the lead screw by four. For a fractional thread, or the pitch of the lead screw is a fractional one, reduce them to a common denominator and use the numerators of the fractions as the pitch of the screw to be cut and the lead screw respectively. If we wanted to cut a thread 25-64 inch pitch and the lead screw is four threads to the inch, that is, the pitch is 1-4 or 16-64. The screws will be in proportion of 25 to 16 and the gears are figured out using 25 per inch as the number of threads on the lead screw and 16 as the number of threads per inch to be cut.

THE CITY OF WELLAND, ONT.

We are in receipt of a neat little book published by the Board of Trade, Welland, showing the growth of the town since the development of Niagara and Cataract Power. Welland is twelve miles from four of the largest electrical power plants in the world. Three are at Niagara Falls—the Canadian Niagara Power Co., whose development consists of 110,000 horse power; the Ontario Power Co., 220,000 h.p.; the Electrical Development Co., 125,000 horse power, and the Cataract Power Co., of De Cew Falls

Welland is a railroad centre and has therefore great facilities for transportation. The Michigan Central, Toronto, Hamilton & Buffalo Railway, the Welland division of the G.T.R. the Wabash, Pere Marquette, C.P.R. and Toronto, Niagara and St. Catharines Electric Railway. Welland is in the centre of the gas belt and smelting companies and foundries are using natural gas from their own mills.

The book gives a list of the present industries, and among others are the Plymouth Cordage Co., Robertson Machinery Co., makers of hoisting engines, the Canada Forge Co., makers of forgings, the Canadian Billings & Spencer, Limited, makers of drop forgings, the Ontario Iron & Steel Co., makers of steel castings, bar steel and rails, the Electro-Metal Makers of Steel, and Page-Hersey Iron Tube and Pipe Company.

J. R. Nelson, who is in charge of the Toronto and Smith's Falls section of the C.P.R., has been appointed superintendent of Muskoka, Owen Sound and Elora divisions. W. K. Thompson, of White River division, succeeds Mr. Nelson.

Gas Engine Flywheels, Their Function and Application

A Treatise on the Importance of Flywheels of Correct Design.

BY GORDAN A. RONAN.

Since the advent of the internal combustion engine, it has been found that a good flywheel is an indispensable feature, in that it provides a means of carrying the piston, crank-shaft, and all other moving parts over the "Dead Centre," and also gives the momentum ne-

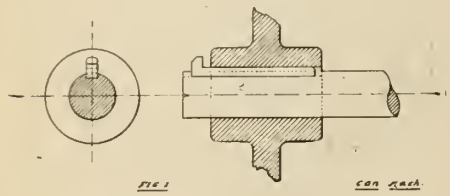


Fig. 1—Common Method.

cessary to carry on the cycle of operations, during the idle intervals, when the engine is preparing for its next impulse.

In addition, the flywheel, when correctly designed, has an element which tends to steady the engine in its operations, and regulates the smooth, even, running of the engine. The flywheel is still further instrumental in absorbing the shocks or impulses which occur at regular intervals in each cycle, and thus eliminates much of the vibration and jar, which would otherwise result, owing to improper flywheel construction.

Flywheel Construction.

A flywheel to be correctly designed should be of the largest possible diameter, proportionate to the engine capacity. This is essential as it gives a great leverage on the crank shaft, and hence more power and effective energy to the engine, which enables the piston to be more easily carried over the point of compression. The flywheel rim should receive the utmost attention, care to have the maximum amount of metal distributed throughout the rim. This should

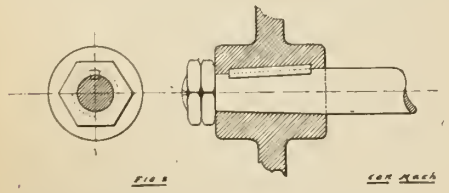

Fig. 2—Second Common Method.

have a wide face and ample side thickness, in combination with the lightest possible web and hub, consistent with safe and efficient construction.

All first-class engine builders have realized the fact, that it does not pay to save metal in their flywheels, but put in every ounce of leverage metal they can and still keep within the above limits of safety and construction.

Some few makers have, however, skimped their flywheels, rendering them much less effective and causing both trouble and annoyance to users when cranking their engines. Their flywheels are too small in diameter, too light in the rim or the weight is placed around the hub or in the web, where it is lost. The result is that these flywheels will not carry the piston over the compression more than a couple of times at most when starting the engine.

Methods—Correct and Incorrect of Application.

The engine buying public is to-day confronted with the almost universal "defective" methods of applying flywheels.

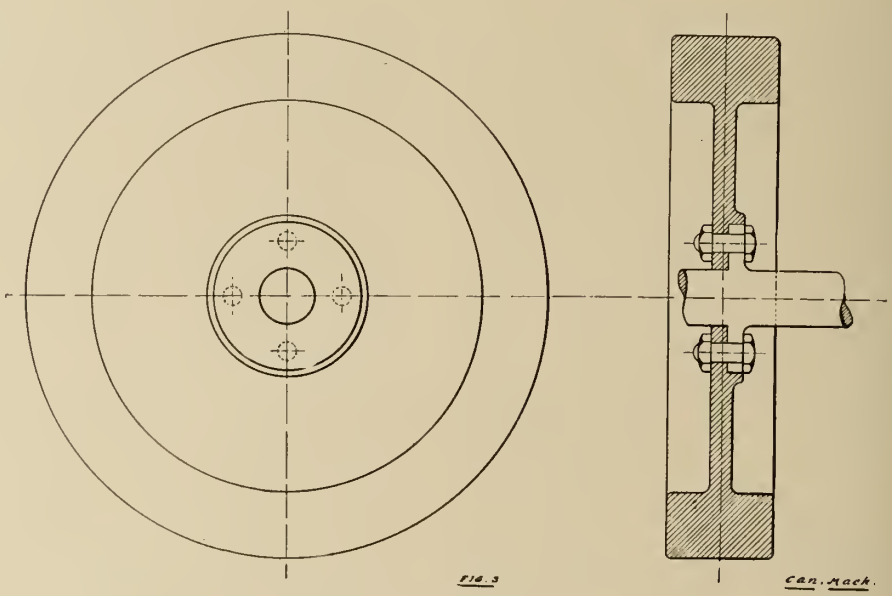

Fig. 3—Ideal Method.

In the following, Figs. 1 and 2, are descriptive of the two most common methods of applying flywheels, both of which are more or less defective, in that each tends in time to wear sidewise, as shown exaggerated in Fig. 4 at A. It will at once appear obvious that a parallel shaft shown in Fig. 1, and fitted with a parallel key to a key-seat, will in the course of time, even with the best of care and atention, tend to assume the above mentioned shape. This is directly due to the fact that the terrific strain thrown upon the crank shaft and bearings, by the desire on the part of the flywheel to go in one direction compelled by the momentum, while the impulse of the piston, when advancing the spark tends to act in the opposite direction.

More especially is this true of marine engines, where the almost universal practice, in small h.p. units is to have them reversible. The key-way must, therefore, tend to wear sideways, and finally wears the key-seat from its original form, marring both the shaft and flywheel oftimes past repair.

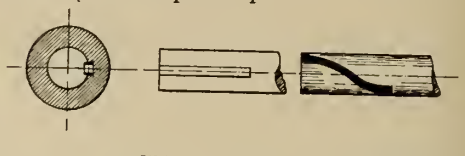

Fig. 4—Result of Wear Using Methods 1 and 2.

A striking example of this has come before the writer's notice during the past week. B, in Fig. 4, shows in exaggerated form what actually occurred to a flywheel keyed as in Fig. 1, when it was suddenly wrenched, by an obstruction taking place in the crank case, the momentum of the flywheel twisted the key, key-seat and shaft one-quarter of its circumference out of the original straight line of key-seat.

The principle of using a taper while much better than the above, is far from being ideal. Some makers anxious to do the public a great favor, have adopted this method in the hope of making it a talking point in their engines. However, this method, too, is subject to loosening of the flywheel by the nuts and key becoming constantly jarred by the engine vibration and the terrific strains on the crank shaft while being reversed. Actual tests have shown the taper to give this annoying trouble also.

A few successful manufacturers in the engine industry who have led the onward march of progress, have given us the ideal method of application as shown in Fig. 3, in which the flanged crank shaft is used, and inserted into an accommodating recess in flywheel. The

four or six holes are first accurately bored to template. and are afterwards carefully reamed. The bolts are machined a neat fit, and the flywheel is then placed in position and locked tight.

The large flange inserted as it is, eliminates entirely the danger of the other two plans, and is more accessible, and easily detached by the amateur, without the marring effect of the chisel, hammer or mall in removing the flywheel when required.

Rope Transmission in the Factory

The Use and Life of Rope for Transmission and Hoisting

Rope drive is coming into favor in some factories with the advent of machinery equipped with change gears. In years past it has not been practicable to use rope drive for lathes, drills or shapers where variable speed is required and when it was obtained by cone pulleys. In cotton mills manila rope has been replacing spur gearing though this latter form is the most exact method of transmitting velocity ratios and gives the highest efficieney when properly made. The rope drive has an advantage of increasing the power delivered to the cutting tool by high initial belt speed. It is an ideal means of supplying power to constant speed shafts. The sheaves occupy less space as they are narrower than those used for belts and this will allow bearings to be placed more closely together, eliminating spring in the shaft. There will be less loss from slipping and the quietness of rope drive is a great contrast to other methods.

Ropes may be arranged in two ways. In the first way there are as many separate ropes as grooves on the pulley In the second method a single rope is wound progressively around the two pulleys, as in Fig. 1, being delivered from the last pulley on one side to the first groove on the other side of the pulley by means of a guide pulley. In the first method if there is one rope used an idler can be inserted to take up the tension, but if more than one rope is required, it is difficult to get the same tension on each rope and one rope transmits more power than another. In the second method the tension is practically equal since the rope is continuous. A device used to keep a tension on the continuous rope drive is an arrangement of three guide pulleys. One is called a "take-up" and its shaft works in blocks in guides. A weight is attached to it and as it is free to move vertically a tension is kept on the rope. This arrangement, shown in Fig. 2, is substituted for "a" in Fig. 1 and one pulley guides the rope from the system to the take-up and the other back to the driving system. Ropes usually used for this drive are 1½ to 2 inches. The net section of the rope is about 9-10 of a circumscribed circle for a 3 strand rope, and in practice a stress of from 140 to 240 pounds per square inch may be allowed on the driving side of the rope. The breaking strain of good cotton ropes is about 4 tons. The speed varies from 3,000 to 5,000 feet per minute. In practice a sheave with a groove of about 45 degrees is used, which gives about three times the friction of the rope running on a flat surface. A rope is made endless by splicing and as every machinist can lace a belt and few can

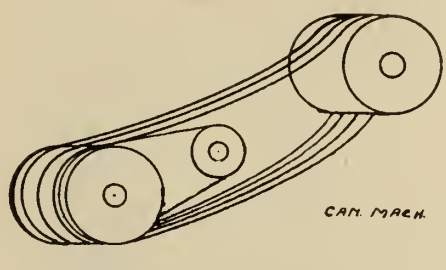

Fig. 1—Method of Keeping Tension on an Endless Drive System.

splice a rope, this is one objection, but the ropes very seldom have to be spliced. One expert rope splicer could attend to more work than a large industrial establishment using rope drive would furnish him.

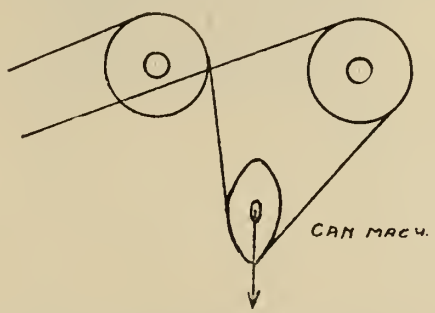

Fig. 2—Loaded Pulley for Tension on Ropes.

The Life of a Rope.

The pulley should never be less than thirty times the diameter of the rope. If smaller sheaves than this are used the power transmitted will be less in proportion. Well cared for, a rope will last fifteen years, though the average life of a rope is about ten to twelve years. With an increase in the diameter of the sheaves there is a material increase in the life of a rope. Lubricating the rope with plumbago mixed with tallow will prevent internal chafing and wear.

Horse-power Transmitted by Good Cotton Rope.

Diam. of Rope in Inches	Velocity in feet per second: 600	1,500	3,000	4,000	5,000
	Horsepower transmitted				
½	.8	2.1	3.7	4.3	4.4
¾	1.9	4.7	8.3	9.8	10.0
1	3.4	8.3	14.9	17.5	18.0
1½	7.7	18.7	33.4	39.2	49.3
2	13.5	32.9	58.7	68.9	70.7

Manila Rope for Hoisting.

In the manufacture of rope the fibres are spun into a yarn which is twisted right hand. From twenty to eighty of these, depending on the size of the rope, are twisted in the opposite direction into a strand. Three or four of these are twisted right hand into a rope. This twisting the parts in opposite directions keeps the rope in its proper form.

When a rope is first used in hoisting there is a tendency for it to untwist and become longer. The first day or two the rope will untwist a certain amount, but after that the length of the rope should remain substantially the same. The four strand rope is most commonly used, both for transmission and hoisting. Hoisting ropes are never spliced, as it is difficult to make a splice that will not pull out.

Practical experience for many years has settled the most economical sizes of rope that should be used. The amount of coal for instance that can be hoisted with a rope varies greatly. With care a rope will hoist from 12,000 to 20,000 tons of coal, but with only ordinary care, only from 6,000 to 9,000 tons. A 1½ inch rope, running on 14 inch sheaves with a strain of 600 pounds per square inch, is found to be economical. Hoisting rope is ordered by the circumference ; transmission rope by the diameter.

CAR FERRY READY.

The new car ferry, Ontario No. 1, built by the Canadian Shipbuilding Company for the Ontario Car Ferry Company, which is to be operated in the interests of the Grand Trunk Railway Company and the Buffalo, Rochester & Pittsburg Railway Company between Cobourg and Charlotte during the year round, left for Cobourg last week to go into commission on the new route.

The big boat will carry coal going north and iron ore and lumber going south, the trip being about sixty miles across the lake one way. The Ontario No. 1 is valued at $375,000.

ACCIDENT ON TORONTO ISLAND.

Cable Snaps, Probably as a result of Crystalizing.

An unfortunate accident, attended with a loss of four lives, occurred on Toronto Island the evening of Nov. 19. A shaft about one hundred feet deep has been sunk on the island to carry a waterworks tunnel under Toronto Bay. A cable snapped when seven men were within fifteen feet of the top, dashing them to the bottom

One end of the false cable was attached to the end of the boom which hung over the shaft. Then the steel cable went through a pulley on the bucket, leading again to the boom and then to the drums of the hoisting engine. It was the portion of the steel cable between the pulley and the end of the boom which gave way. The rigging is that which is commonly employed in all such shaft work, and is considered sufficiently safe.

The broken cable is supposed to have a working tensile strain of twenty-one tons. The cables were examined hourly and if one strand was broken it was immediately replaced by a new cable, one being always kept on hand.

Causes of Cables Breaking.

The manner in which the cable snapped would lead one to believe that the steel in the cable crystallized. The writer has seen within the past few months a practically new cable draw apart, precipitating five men a distance of about thirty feet and injuring all five. Sometimes the cause of cables breaking is due to running over small sheaves, causing internal strains. These break the inner strands and this can only be recognized by the creaking sounds of the cable. The parting of the cable when this is the cause is by the drawing apart of the strands.

It is a well known fact that if a bar of iron be tapped on the end the molecules of iron will arrange themselves in such manner that the bar becomes a magnet. Something of the same takes place in the iron posts supporting a building. From the break, straight across the strands we should judge that the molecules in the steel had in some such manner arranged themselves. In other words, the steel had crystallized. The crystallizing may be caused by the constant bending of the cable, causing the molecules to arrange themselves in a certain position, the carbon changing its physical state. When a rearrangement takes place an unusual strain will fracture the steel. This is what probably happened in this case. The carbon has crystallized out forming a coarser structure with a lower tensile strength and with the strain coming upon it the cable snapped at this weak spot thus formed.

DEATH OF MR. F. B. POLSON.

The President of the Polson Iron Works. Limited. Toronto, died suddenly on October 28th at his residence, 6 Beaumont road. Mr. Polson occupied a prominent position in commercial circles as president and general manager of the well known ship-building and engineering firm, the Polson Iron Works. He was born at Port Hope, Ontario, on February 10, 1858. so that he lacked but a few months of being 50 years of age. He was a son of William Polson, who was mechanical superintendent of the Grand

THE LATE MR. F. B. POLSON.

Junction Railway at Belleville before founding the present business in conjunction with his son.

The Polson Iron Works. Limited, was established in 1883. under the name of William Polson & Co., the members of the firm being William and his son Franklin Bates Polson.

The firm started work on the Esplanade at the foot of Jarvis St., where a general machinery trade and yacht building business was carried on. The business grew so rapidly, however. that in 1885 a joint stock company was formed. A new site was obtained at the foot of Sherbourne St. and suitable buildings erected thereon for carrying on the business of engineers, boiler makers and ship builders.

Mr. F. B. Polson received his education in the Cobourg Public School and Collegiate Institute. He was a mechanical engineer of thirty years' standing, held marine engineers' and masters' papers, and was a member of the Institute of Naval Architects of London, England; Engineers' Club, New York; Canadian Society of Civil Engineers; and the Toronto Board of Trade. He took a very active interest in technical education, being for some time chairman of the Toronto Technical School Board. He was a member of the National Trades Association and the Employers' Association of Toronto. Mr. Polson served a lengthy apprenticeship with railway and manufacturing companies, and gained an experience in ten years that fitted him for the position of mechanical superintendent of the Victoria Railway at Lindsay. This position he resigned to found with his father the shipbuilding business. They undertook and completed important contracts, such as the magnificent steel steamer Manitoba for the C.P.R., the Petrel, the J. Israel Tarte, and many others. The industry has grown to be one of the largest of its class in Canada.

Mr. Polson was laid to rest in the family plot, St. James Cemetery, October 30.

The business will continue under the presidency of Mr. J. B. Miller, and the management of Mr. J. J. Main.

PERSONALS.

M. S. Blaiklock has been appointed engineer of maintenance of way for the G.T.R., with office in Montreal.

H. E. Whittenberger has been appointed superintendent of the eastern division of the G.T.R., with office in Montreal.

Cecil B. Smith, of Toronto, has been engaged by the city council of Port Arthur to make a preliminary survey of Dog Lake, which will give a head of 340 feet. It is, therefore, of much larger power than Kakabeka Falls, which gives a head of 185 feet.

Richard D. Hurley, manager of the Pittsburg office of the Independent Pneumatic Tool Co., of Chicago, died suddenly in Chicago on Nov. 5th. He was a young man, but had been with the company over ten years and made a wide circle of friends.

Harvey Graham, assistant general manager and director of the Nova Scotia Steel Company, died at his home in New Glasgow, Thursday morning, Oct. 31st. He was connected with the large coal, iron and steel industries for many years.

E. Hallman has just returned from a business trip to northern and western Ontario for H. W. Petrie, Limited, Toronto, and reports business in machinery lines active in Fort William, Port Arthur, Sudbury, North Bay and Cobalt.

MACHINE SHOP METHODS AND DEVICES

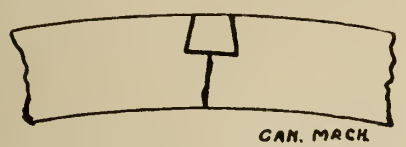
REPAIRING A CRACKED WATER JACKET.

By E. S. Cooper.

Just at this season of the year, when you are apt to think it is not going to freeze, is the time that nearly all splitting of water jackets on gasolene engines occur. In the middle of winter it is generally taken for granted that there is danger from freezing all the time the water is left on when the engine is not running and it becomes a habit to drain off the jacket water when shutting down the engine for the night or for any great length of time. In spite of all personal precautions on the part of the owner, or careful and oft-repeated instructions to employes, there is apt to come a time when the jacket water is left in the cylinder on a cold night and the inevitable happens.

The cracks in the jacket take all kinds of shapes and occur on all sides of it. Sometimes they run into the face of the cylinder against which the cylinder head is bolted and this allows the



Repairing Crack in a Gas Engine Water Jacket.

casting often to spring so badly that the job of repairing it is almost impossible.

The usual method of repairing a cracked water jacket is to bolt a band around it and draw the edge together tight enough to prevent a leak. This accomplishes its purpose, but makes an unsightly job and one that detracts from the value of the engine if it is ever wished to sell it. If the job is done so that the repair does not stand up above the body of the casting it can be painted over and never show.

One method we used in order to do this was to cut a dovetail groove all along the crack, leaving the crack in the centre of it. A piece of copper wire was then taken, annealed by bringing it to a red heat in the blacksmith's fire, and plunging it into cold water, hammered to a square so as to just fit the groove, annealed again and driven into place. It was left so that when hard on the bottom of the groove the top of the copper stands slightly above the casting, and it was then peened until the copper metal flowed into and filled the dovetail of the groove.

The top can then be dressed off and painted over, and, if the job has been properly done, will hold as well as ever. We know of some jobs done this way that have stood for 3 or 4 years and seem to be in as good shape now as when first done.

One of our repair men hit on a plan of filling the groove that was much simpler than the one described above and which proved quite a practical success. After the groove was cut, instead of all the fitting of the copper, it was simply filled with smooth-on iron cement and allowed to stand over night. In the morning it was dressed off, painted, and as far as we know, these jobs have held and stayed right.

When you see some of the large patches put on some gasolene engine cylinders

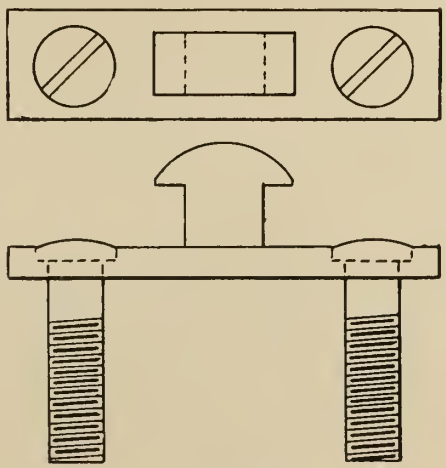


Fig. 2. For saddle.

just try and figure out the amount of time it took to drill and tap all the holes in the casting and to fit and drill the patch. Not only is it an unsightly job but the groove can be cut and filled with the iron cement in one-quarter of the time and is much neater when done.

The above sketch shows very plainly how the groove was made in relation to the crack in the wall of the water jacket. A 3-16 inch or ¼ inch capechisel is used to cut the groove to the proper depth and a side cut chisel easily undercuts the dovetail. It is not necessary to smooth the groove out at all, and the fact of not having to do any fitting on it, when using the iron cement, makes it possible to do a quick job with the simplest of tools.

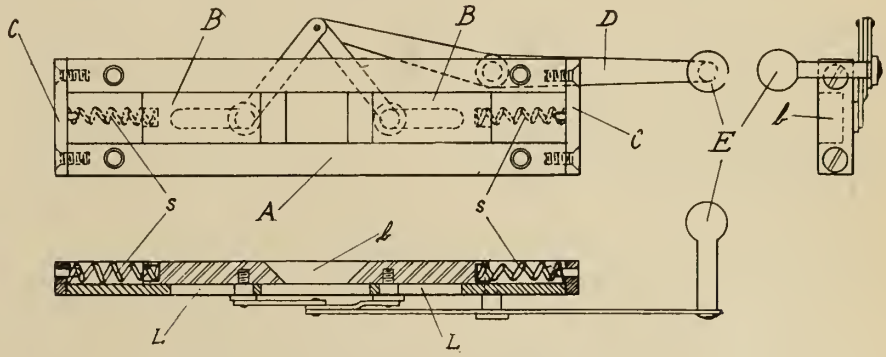

Fig. 1—For Tail-stock.

ATTACHMENT FOR DRILLING.

By R. Prosser.

The accompanying drawings show a fixture which could be applied to an engine lathe, where there is any great amount of drilling done with the tail-stock.

In Fig. 1 is shown part of the fixture to be fastened to the tail-stock by screws, A A, Fig. 4. A is a plain block shaped out at B, to receive the sliding blocks B B.

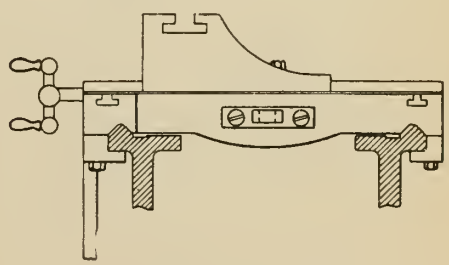

Fig. 3—Attachment on Saddle.

C C are strips fastened on the ends of A to back up springs S S which are kept in place by recess and dowel-pin as shown. D is a lever (moved by handle E) to act on toggle joint to move blocks B B back and forward. Slots L L act as a guide to keep blocks in position. Fig. 2 shows part to be fastened to saddle as shown in Fig. 3. If possible, Fig. 1 could be placed on the inside of tail-stock to avoid removing it when not in use.

When drilling is to be done bolt Fig. 2 to saddle, start drill in the usual way by centreing, then take saddle back and snap saddle and tail-stock together, thus locking them and proceed to drill with saddle feed. To unlock saddle from tail-stock, raise handle E and remove saddle. Gib G could be used to prevent tail-stock getting out of line, as the king bolt in tail-stock must be a

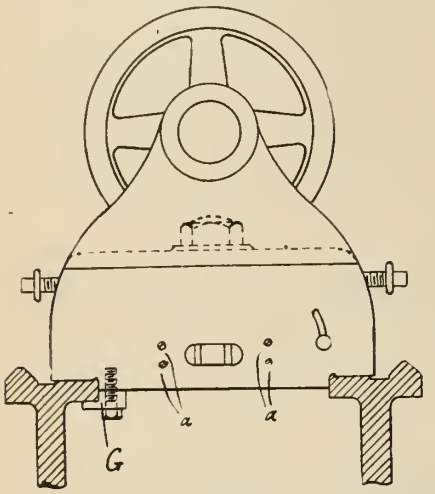

Fig. 4—Position of Screws on Tail-stock

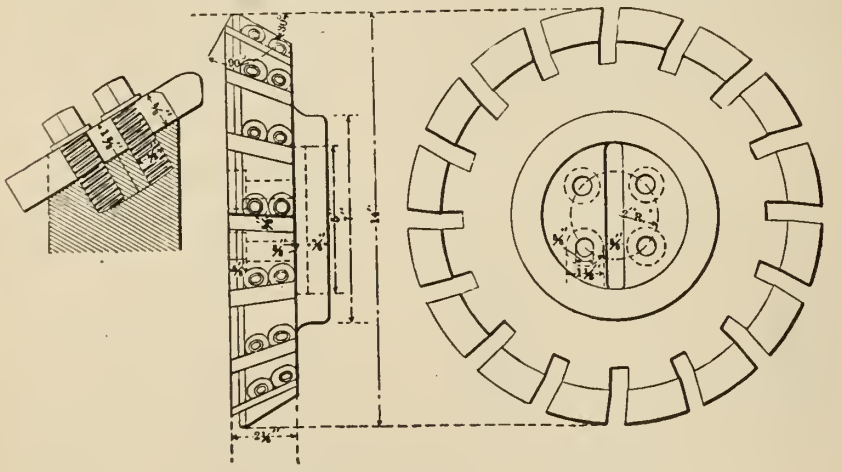
little slack when drilling in this manner. The appliance must be modified to suit different makes of lathes.

AN INSERTED-TOOTH FACE-MILLING CUTTER.

The accompanying illustration shows a 14-inch face mill devoid of all frills and ruffles, but which has been in constant use for the past six months and has given entire satisfaction. The system of holding the cutters is as simple as it is possible to get and have them hold, and the fact that we have broken several $\frac{5}{8}$-inch square cutters and never had one slip back is evidence enough that the cutters cannot move. The slots are milled a good snug fit for $\frac{5}{8}$-inch square tool steel and the holes for the collar screws are counterbored about 1-32 inch below the top of the cutter so the screw will tighten up on the cutter before it strikes its seat in the body. The cutters are ground to a gauge and set in the body to another gauge so that when one set gets dull another can be put in with the assurance that each cutter will do its share of the work. The cutters are ground like a lathe roughing tool, leaving a round nose and doing away with all sharp corners, which, I believe, is the cause of most face mills getting dull so soon: the sharp corner burns off and leaves the cutter without any cutting edge.

With a cutter ground in the shape here shown, it is possible to remove $\frac{1}{2}$ inch of cast steel at a cut with a feed of 2 inches per minute, and if some good drill compound be used to flood the cutter, it is remarkable how long a set of cutters will last without sharpening.—H. M. L. in American Machinist.



An Inserted-tooth Face-milling Cutter.

USEFUL CONSTANTS.

By J. H. R., Hamilton.

Some times, after a man has spent considerable time on a job and cut away a lot of stock from the same, the foreman comes along and asks him for the weight of the material, or when he comes to fill out his time slip, he either has to tell the foreman that he forgot to weigh the stock or (if no table of weights are at hand), make a guess at it.

Now, here are a few simple constants which only vary a fraction of a pound in a hundred:

Weight in lbs. per 1 ft. of length:

For Square Iron—Square one side and multiply by 3.333.

For Round Iron—Square the diamter and multiply by 2.6175.

For Machine Steel—Add about 2 per cent.

The areas of squares or circles vary as the squares of their sides or diameters.

A square 3 inches on a side is 9 times as large as one 1 inch on a side.

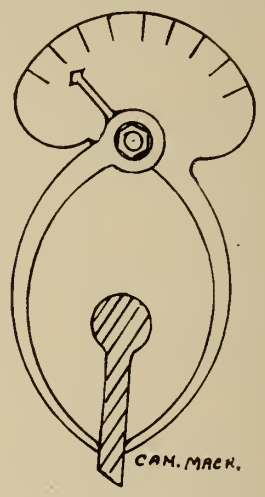
A circles 5 inches in diameter is 25 times as large as one 1 inch in diameter.

Therefore, the weights of material vary in the same proportions.

HOME-MADE CALIPERS.

By a Subscriber.

I had much difficulty measuring the thickness of iron when a flange was cast



A Handy Pair of Calipers.

along the edge, and made a pair of calipers, as shown in sketch, to overcome the trouble. On the top of one arm of the calipers I filed out a circular plate and on the other an arrow, fastening the two arms together with a small piece of paper brass between to make them work smoothly. To get the thickness marks on the plate, I closed the calipers and marked with a line opposite the arrow; then I took a scale, opened the calipers to each one-eighth and put a permanent mark opposite the arrow each time. If anyone wishes smaller divisions, the plate can be marked in sixteenths. By direct reading I could then tell at once the thickness of the metal. The sketch shows the calipers in use, showing the thickness of the iron to be one-eighth of an inch.

HOW SHOULD GLOBE VALVES BE PLACED?

All globe or angle valves for steam or gas pressures should be placed so that the pressure comes on the under side of the disk. The main reason is that when the pressure is below the disk, the valve will almost invariably seat better, as, when the steam enters above the disk and the valve is nearly seated, the rushing steam has a tendency to blow a little harder through one side, owing to the whirling motion it attains, and this causes the disk to seat improperly by one side seating a little ahead of the other.

Some engineers argue that the pressure helps to press the disk down on the valve seat when the pressure is above the disk, but if the valve leaks when turned down as tightly as it can be turned by the handle, it is time to regrind the valve, or put in a new disk, as the case may be.

I have had several experiences with the disk becoming detached from the stem, and in one case, it was in the water-supply pipe between the feed-pump and the boiler, or, rather, between the check-valve and the boiler. It immediately blew the packing out of the feed-pump, and it being the only source of supply to the boiler, we had to shut down the plant for nearly a whole day, so the valve could be repaired.

Had the valve been placed the other way the disk would have acted as a check-valve and we could have kept running until a convenient time for repairing.—M. Johnson, in Power.

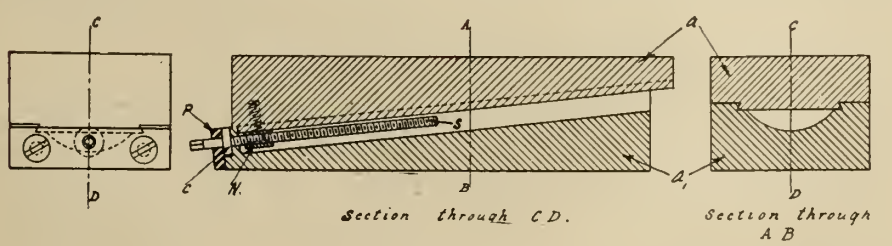
PARALLEL BARS FOR PLANER.

By J. H. R., Hamilton.

The accompanying sketch shows an adjustable parallel strip which has been used in the shop for quite a long while As it is a very useful tool for supporting planed pieces on the planer or shaper, and does away with a lot of packing up with washers and pieces of tin, etc., being very easily and quickly adjusted to any desired size within the limit of the adjusting screw.

As is shown in the sketch, the tool consists of 2 pieces of cast iron, a and a, planed and dovetailed at an angle with the faces about ¾ inch or 1 inch taper to the foot, making a fairly tight fit, thus avoiding a gib. The adjustment is made by turning screw S, which works in nut N, fastened to top block by two screws. Collar C is placed in a recess in A, and plate P fastened on the end to support screw S and avoid end play.

The two in the shop have been in use for a number of years and are as good as new. Such a strip with careful handling would last a long time.



Parallel Bar for Planer.

POWER REQUIRED FOR MILLING MACHINES.

The following experiments by S. Streiff, in "Werkstatts-Technik," for finding the power required for driving milling cutters have been carried out on a special milling machine. The results are given in the accompanying table. Only the results of such experiments where the power required was determined definitely are taken into consideration. A number of experiments, where either the time of cutting was insufficient to get a good average, or where some other disturbing factor entered in the experiment, have been left out of consideration. The milling cutters used were made from high-speed steel. It will be seen from the table that a proportionally higher amount of power is required for light milling than for heavy, a result that is rather natural, as the running of the machine itself, irrespective of the work being performed, would require practically the same amount of power in either case. It will also be seen from the table that the depth of the cut does not increase the power required in the same proportion as does the width of the cut, and that work with a heavy feed and a deep but comparatively narrow cut requires far less power for the amount of metal removed than does a slow feed, and a cut of moderate depth, but wide. In general, it seems as if a slow feed is particularly uneconomical in the use of the milling machine. The figures in the table have been transformed into the English system of measurements, to facilitate comparisons.

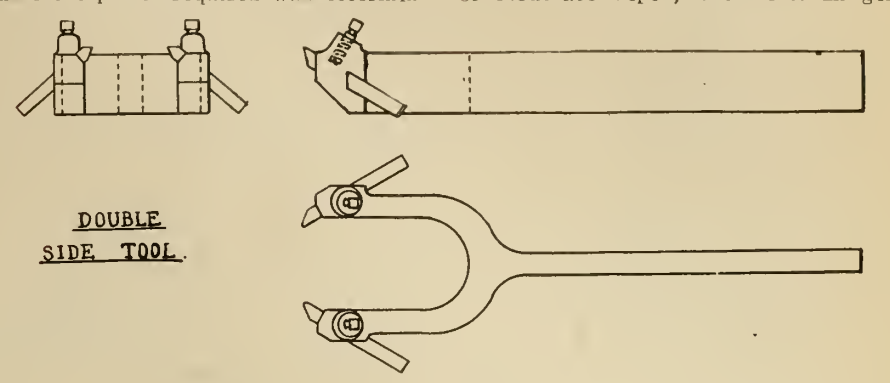
Table of Milling Machine Experiments, Showing Relation Between Feed, Depth of Cut, and Power Required.



THE DOUBLE SIDE-TOOL.

By R. Prosser.

The double side-tool is a most useful tool, and is very easily made. In doing a job that has to be faced off on both sides, use the double side-tool. It does both sides at once and takes no more time than to do one side. The tool will do different sized jobs by loosening the set screws and moving tools to desired size.

TO BORE A BLIND HOLE.

By A. E. D.

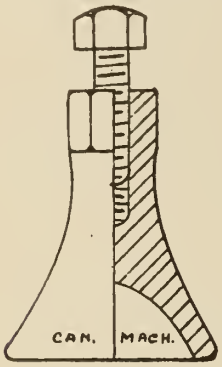
When boring a small cylinder or cutting a blind hole where there is no clearance and the thread ends against an internal shoulder, it is a hard matter to watch the tool itself. I have found it to advantage to run the tool in against the shoulder and chalk a mark on the lathe saddle and another on the bed, and then put a line with a lead pencil or a scriber, if one does not mind marking up the machine. When the two lines on saddle and bed coincide in feeding, the cutting tool has reached the end of its travel.

A HANDY JACK.

By Machinist.

A device that I have used in the machine shop for leveling work when drilling and planing is a small lifting jack that we cast in our own foundry. We made them in several sizes and the illustration will show the construction. The top is hexagonal so that a wrench may be used to prevent the jack from turning when the bolt is turned to raise or lower the work. An ordinary hexagonal-headed bolt is used with the head rounded on the top. Work can

be easily and quickly leveled up by means of this device. For one job on the planer where we had a number of pieces

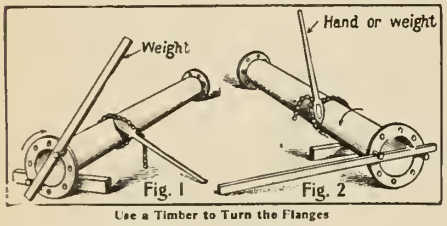


A Handy Jack.

to plane we bored holes in the base of the jack and bolted it in position on the planer.

SCREWING FLANGES ON PIPE.

It is unnecessary to tie the handle of the chain tongs to a post. The practical way to arrange the pipe and tongs would be to place the tongs as shown in Fig. 1, so that they will hold the pipe from turning, and then allow the handle of the tongs to rest on the floor,



Use a Timber to Turn the Flanges

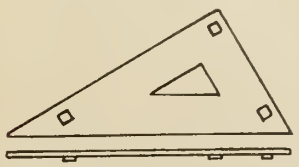
using the timber to turn the flange, says a correspondent in the Metal Worker.

Another way would be to allow the end of the plank to rest on the floor, and the workmen could use the tongs to turn the pipe into the flange, the flange being held stationary by the timber, as in Fig. 2.

SQUARE ARRANGED FOR RULING.

By a Draftsman.

When inking in drawings and tracings I was often troubled with the ink flowing along the edge of the square. I successfully overcame this difficulty by glueing on the square three small pieces of cardboard as shown in the illustration. The cardboard pieces are about one-sixteenth of an inch from the edge of the square. I am never troubled with the ink flowing along the square now. In addition with this arrangement I can ink in lines crossing each other without fear of blotting.



A Handy Square Attachment.

WESTERN MACHINERY MARKET.

Winnipeg, Nov. 22.—The year just closing has not been the most prosperous on record for the machinery trade of western Canada, but has been quite as good as could have been expected under the particular conditions obtaining this year.

The machine tool trade in the west is good and selling agents generally report good sales. Business in this line has kept up, especially on account of the railroad shops, which are kept busy.

Production in the lumber mills has been curtailed owing to the lessened demand for building material, due to various causes, which are well understood and which, therefore, need not be dealt with here. Dull times in the lumbering industry has meant a decrease in the orders for wood-working machinery from the mills at the coast and in the north country. At the present time the coast lumbering industry is not in the best shape and the machinery interests are unable to secure their usual large orders from that quarter. It is recognized that the depression in this industry is merely temporary and conditions are bound to improve very soon, but it is none the less a fact that at the present time the machinery dealers find their business with the lumber and allied industries far from satisfactory.

Sales of mining machinery have been affected by the condition of the copper mining industry in southern British Columbia. The closing of the Granby smelter and the reduced output of the mines at Rossland and Grand Forks, due to the low market price of the metal have had a corresponding effect on the demand for mining machinery. In this case also it is believed that present conditions are temporary and relief may soon be expected, but there is depression at present, and the machinery trade feels the effects. On the other hand the coal mining industry is in fairly satisfactory condition.

Elevators and flour mills provide a good market in the west for machinery. This year sales of this class of machinery have been large, but owing to the unsatisfactory crop outlook they have scarcely been as large as in previous years.

Machinery trade in the west is, therefore, not in the most satisfactory condition at present. It must not, however, be thought that the outlook is discouraging. An examination of the causes responsible for the slight depression now felt shows clearly that these causes are temporary in their nature. Once removed, their effect will disappear and business will once again be on a normal basis. It has been an exceptional year, a year in which a combination of unfortunate circumstances has checked the natural expansion of all classes of business and the machinery trade has suffered with the rest. But the country is in sound condition and the prospects for 1908 are more encouraging.

BOOK REVIEWS.

GAS AND OIL ENGINES AND GAS PRODUCERS—By L. S. Marks and S. S. Wyer. 143 pages. 6½x9½ inches. Illustrated. Published by the American School of Correspondence, Chicago, Ill. Price, $1.00.

Part I, by Prof. Marks, reviews the developments of the gas, gasoline and oil engines and the Thermodynamics of the Otto cycle and its later development, the Diesel cycle. Part II, by Prof. Wyer, treats gaseous fuels and producer gas and its manufacture. To those who wish to avail themselves of the developments along these lines we recommend this book.

ELEMENTS OF MECHANICS.—Published by the Macmillan Company, of Canada, Limited, 27 Richmond street west, Toronto, Ontario, 280 pages, cloth covers, 6x9 inches, price net $1.50. The book is written by W. S. Franklin and Barry Macnutt, and illustrated throughout, over 180 cuts being used. The work covers the measurement of length, angle, mass and time, physical arithmetic, simple statics, translatory motion, friction, work and energy, rotatory motion, elasticity of materials, hydrostatics, hydraulics, wave and oscillatory motion. This last topic is treated in minutest detail, and is one of the most valuable chapters in the book. The work is prepared to be of service for both colleges and technical schools. Practical problems with explanations are given on locomotive curves, engines, friction, the gyroscope and on all the various topics treated. The work is comprehensive, and explains in a thorough manner, the fundamental principles of mechanics, with their applications to actual apparatus in daily use and to engineering problems. The endeavor of the authors has been to make a dry subject interesting, and in this they have succeeded, giving both a mathematical and descriptive treatise of the laws governing the field of mechanics.

DEVELOPMENTS IN MACHINERY

Metal Working Wood Working Power and Transmission

LARGEST PLANER BUILT IN CANADA.

Some months ago there was dismantled for shipment in the works of John Bertram & Sons, Limited. Dundas, Ont., a planer of such immense proportions that one was naturally led to make enquiries concerning it. This planer is now doing service in the plant of the Canadian Westinghouse Co., Hamilton, and is unique among Canadian manufacturers for its size and detail construction. Not only is it the largest planer built in Canada, but it is also the largest in use in Canada.

The planer is 10 ft. 2 in. between housings and under cross-rail, and is equipped with a 20-ft. table. The construction and equipment is modern in every respect. It is motor driven with a 50 h.-p. variable speed D.C. motor. The cross-rail is raised and lowered by means of separate motor. There is also a motor provided for quick movement of side head, and also one for movement of cross-rail tool head.

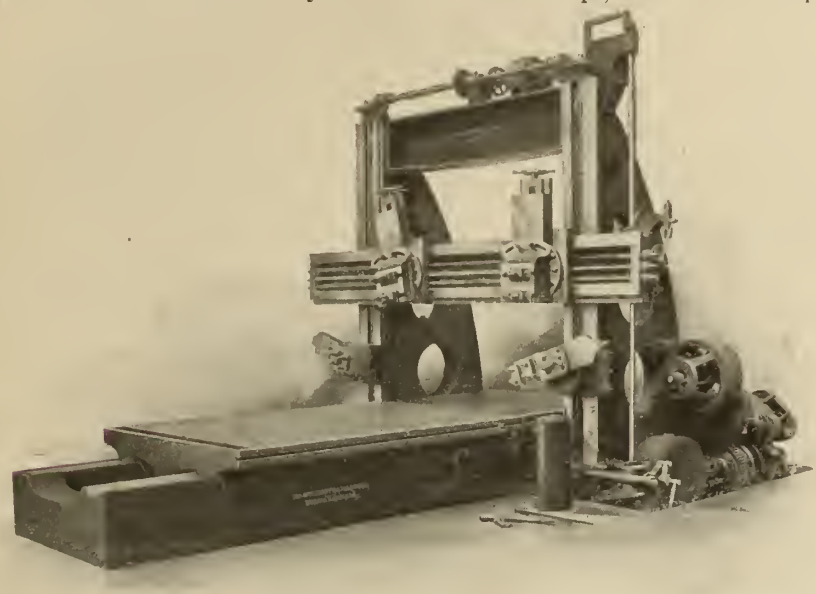
The main drive is through gearing, and the planer is controlled by means of a pneumatic clutch. This pneumatic clutch is something new in Canadian shops, and is only used in the States on large planers. The gearing and rack are of cast steel, and are thoroughly encased to ensure against damage.

The table rests on one "V" and one flat surface, a common style of construction in large planers. The V and flat surface are provided with rollers for lubricating.

When working under full load this planer is capable of removing, in cast iron, 4 cuts, 1½-in. deep. The planer can be reversed to a line, showing the exactness of the pneumatic clutch.

The making of this planer occupied no little time and no little space in the Bertram shops, and was completely erected and operated for a month before it was dismantled and shipped.

Additional ideas of the size of this machine can be obtained from the weight, 200,000 pounds.



The Largest Planer Built in Canada—John Bertram & Sons Co., Dundas, Int.

—

THE BATEMAN HIGH SPEED PLANER.

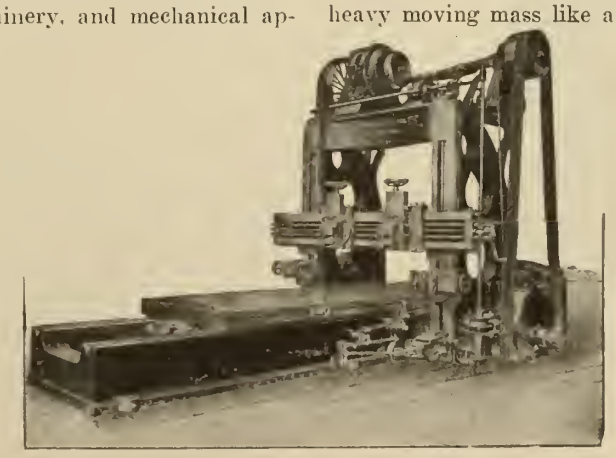
In the construction of all kinds of engines, machinery, and mechanical appliances there are many flat surfaces to be machined, and manufacturers have a choice of several types of machines for doing this work. These machines can be divided into two leading classes, i.e., reciprocating machines, such as planers, slotters and shapers and rotary machines, comprising all the different kinds of milling machines.

The introduction of high-speed steels has completely upset old standards, and made possible greater and better production from planers equally with other tools. A modern planing machine must now be capable of taking full advantage of the best brands of tool steel, and cutting speeds must be aimed at which are at least equal to the cutting speed of a lathe using tools made from the same brands of high-speed steel. The return speed should also be rapid, so that very little time be wasted over the idle stroke, and the time lost at reversal should be reduced to a minimum.

The makers of the Bateman High-speed Planers put upon the market an exceptionally rigid and massively designed tool, and by means of two patent attachments have succeeded in attaining cutting speeds as high as high-speed steels will allow in conjunction with quick return speeds. This is accomplished without the consumption of an excessive amount of power.

The table of this machine varies from the usual construction, in that the rack, instead of being rigidly fixed to the table is attached through springs. The baffer action of these springs enables the table to be stopped and reversed without any jar, and at the same time so lessens the shock upon the gearing that very high speeds are attained without risk of failure in the gearing.

The reversing at high speeds of a heavy moving mass like a loaded planer table calls for increased energy, but the makers ingeniously meet this difficulty by fitting two heavy flywheels at either



The Bateman Planer—Leeds, Eng.

side of the machine, instead of ordinary loose pulleys. These flywheels at each reversal are coupled to the fixed pulley by the belt, which overlaps both pulleys, and by the contract of cone clutch faces, between the fast pulleys and the fly wheels. The energy stored in the flywheels is utilized effectively in stopping and reversing the table, thus equalizing the power required for driving.

The general excellence of the design and build fits this planer for very heavy work, while the high cutting and return speeds enormously increase its earning capacity. The importance of the absence of chatter is generally recognized, and the makers, with this object in view, devote special attention to the bedding down of the v-slides and other parts concerned.

This illustration is one of three 84-in. x 72-in. x 16 feet motor-driven machines working at a cutting speed of 45 feet per minute, with a return speed of 110 feet per minute.

This planer is manufactured by The Bateman Machine Tool Co., Leeds, England.

VICTOR PIPE MACHINE.

The Loew Victor Pipe Machines, manufactured in both hand and power types, have many features of interest. The die head is designed on the principle of the universal chuck, and an automatic device releases the dies after the thread is cut and removes burrs from the thread. Power is transmitted in such

Victor Pipe Machine.

a manner that insures a maximum amount of power and renders the machine noiseless in operation.

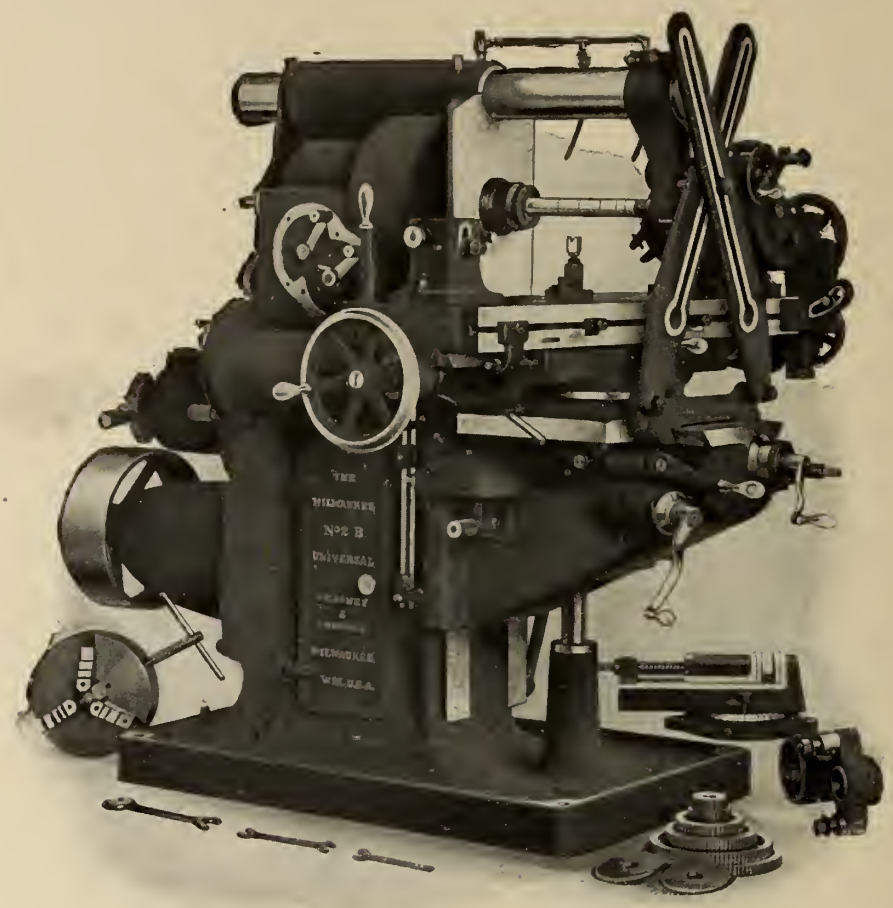
All the Loew Victor Pipe Machines are now being equipped with cut-off attachment, which extends down through the solid portion of the die head in a manner similar to that of the dies. When the cut-off is in use the pipe is centred by an adjustable self-locking guide, similar to the self-locking feature of the die head, which obviates the necessity of using bushings.

One of the new styles, just placed on the market, is the No. 0 power machine, for cutting and threading ¼ to 2-inch pipe, shown in the accompanying cut. This machine has been designed principally for pipe machine users who really desire a power driven machine that will take small sizes and yet do not care to go to the expense of a large lathe-bed outfit. The No. 0 machine is moderate in price, in fact, so inexpensive that everyone having use for a machine of this type can afford to own one.

Additional new types will be placed on the market to complete their line in pipe threading machinery. A catalogue of these machines may be had by applying to the manufacturers, the Leow Manufacturing Co., Cleveland, Ohio.

NEW TYPE UNIVERSAL MILLING MACHINE.

The accompanying cuts represent a milling machine with some new and commendable features. The distinctly new feature of the machine is the absence of a counter shaft, the machine being directly connected from the line shaft to a pulley shown on the machine. On this account the machine can be brought into operation very quickly and the expense and inconvenience of overhead pulleys is done away with. The driving pulley may be replaced by direct motor drive if such is desired.



New Type Universal Milling Machine.

Three styles are being placed on the market, manufacturer's, plain and universal. In the manufacturer's milling machine there is no up and down feed to the knee, the plain has all automatic feeds and the universal as shown in our illustration is the same as the plain with a table that swivels, making it a universal. The three styles are made from the same pattern, differing in the attachments.

The speed change gears are enclosed in an oil tight reservoir in the bottom of the machine frame and from this the machine oil is pumped to all gearing and bearings, keeping them flooded with oil. This pump is a smple spur-gear and pumps the oil through channels in the framework to parts requiring lubrication.

The three types have automatic cross vertical and table feed, and are equipped with stops at the end of the stroke for all feeds and an adjustable stop trips the feed at any point desired. No two feeds can be used at the same time

and the stops cannot be removed from the machine so that the operator cannot omit them.

The Universal Milling machine is installed in the Allis Chalmers, of Milwaukee, and Warney & Swasey, Cleveland, and is used largely in tool room work for milling tool steel. A pump is supplied with each machine as the proper lubrication of tools largely increases the output.

The feed is constant speed, independent of the spindle speed. The feed can be manipulated in combination with the spindle speeds to a fractional degree. Vertical milling attachments can be furnished with the universal, if desired, thus combining all the features of a horizontal and vertical milling machine.

The milling machine may be used to cut large gears. The index rotary table is made strong and rigid for the cutting of these large gears. The indexing plate interchanges with the dividing centres. Accurate divisions can be made to within one minute of arc. The rotary table has power feed for circular milling.

These milling machines are manufactured by Kearney & Trecker, and are now being placed on the Canadian market by A. R. Williams Machinery Co., Montreal, Toronto and Winnipeg.

SAFETY YIELDABLE SLIP GEAR.

The Yieldable Slip Gear is a safety device for use in machines of many types and is intended to replace friction clutches and shearing pins. It is used in any mechanism where it is necessary to have some point yield to prevent other parts from breaking.

Fig. 1 shows the disassembled slip gear and gives an idea of the construction. The cast iron body in the centre is keyed to the shaft and has four holes in which are seated springs contained within hollow bushings, which they press outward. The construction is better shown in the line drawing, Fig. 3. These hollow bushings have seats at the outer end in which rest balls which are pressed against the face of the gear mounted on the shaft. The twelve seats for the balls are shown in the gear in Fig. 1. The shaft drives the gear, or the gear the shaft unless the driving power becomes great enough to force the balls from the seats in the web of the gear against the pressure of the springs which hold the balls in the seats. The power which may be transmitted without displacing the balls is regulated by a nut which bears against the plungers on which the springs are seated and which increases or decreases the compression.

The safety gear is applicable to any feed or speed device and is especially for use on mechanism liable to shock or sudden over-load, electrically driven machines and automatic machinery. It has an advantage over the crank pin and is always ready in case of emergency to counteract any undue strain. It can be easily applied to any machine without altering its design and as it is adjustable it can be changed to suit any new conditions. Fig. 2 shows an assembled view of the yieldable gear.

Patent rights have been granted in United States and foreign patents are pending. The safety yieldable gear is manufactured by the Yieldable Gear Co., Springfield, Ohio.

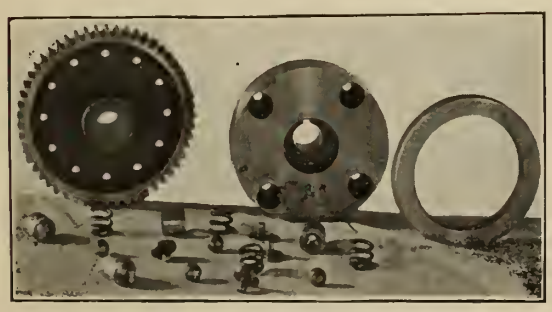


Fig. 1—Disassembled Slip Gears.

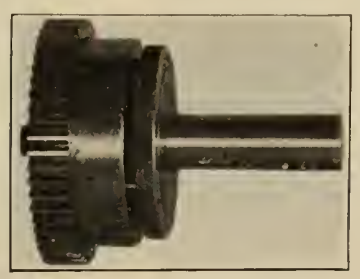

Fig. 2—Safety Slip Gear.

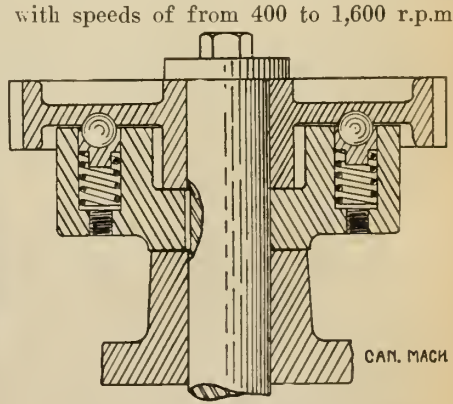

Fig. 3—Section of Yieldable Gear.

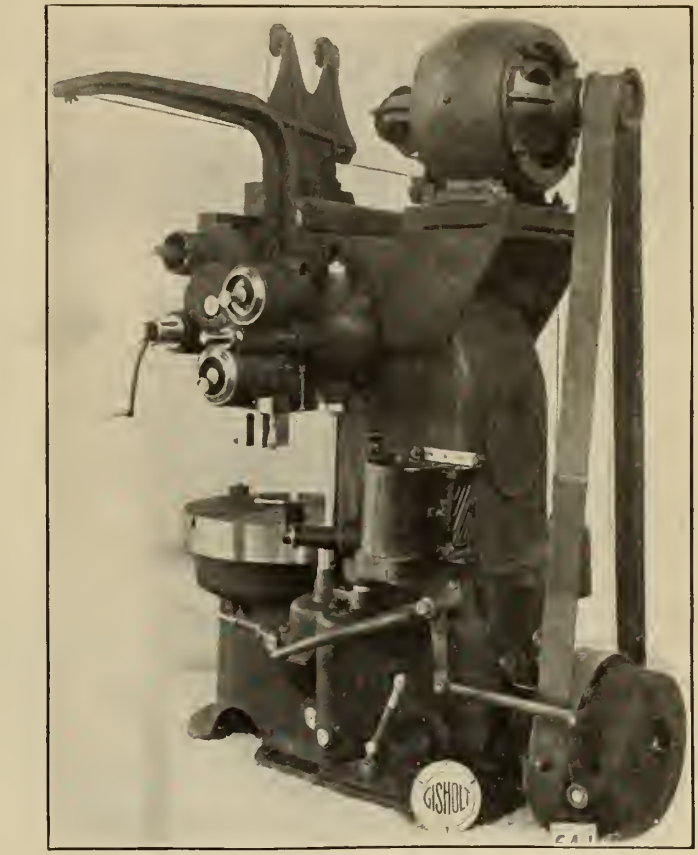

The Gisholt Motor-driven Boring Mill.

MOTOR-DRIVEN BORING AND TURNING MILL.

The boring and turning mill here shown with motor drive, is one of the latest placed on the market. The motor is a 5 h.-p., variable speed. 4 to 1 motor with speeds of from 400 to 1,600 r.p.m. On this form of drive a single friction pulley controlled by a lever, as shown, is substituted for the three step cone pulley used on the belt-driven machine. Through the friction device provided on the motor-driven machine, the table is

under the absolute control of the operator and may be started, stopped or moved any fractional part of a revolution. Owing to the position of the motor as mounted no additional floor space is required, the machne being self-contained.

tion without the use of a scale. By means of the feed tripping device any feed may be positively or automatically stopped at any predetermined point; the dials for controlling feed trip may be plainly seen at the end of the cross rail. This device will also trip any feed

GRANT-LEES AUTOMATIC GEAR CUTTER.

This new gear-cutter is the first successful machine built on the principle of cutting gears with a hob, hat has been placed on the market. It is dif-

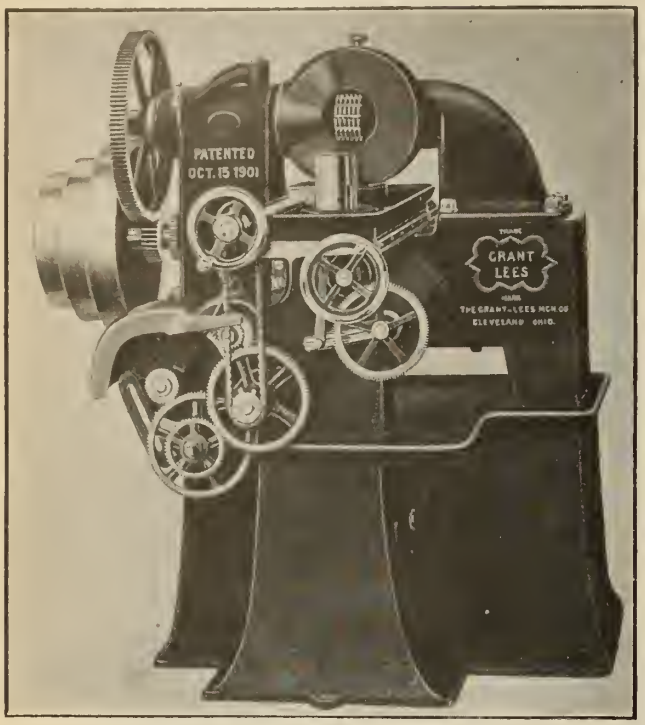

Fig. 1—Front of the Automatic Gear Cutter.

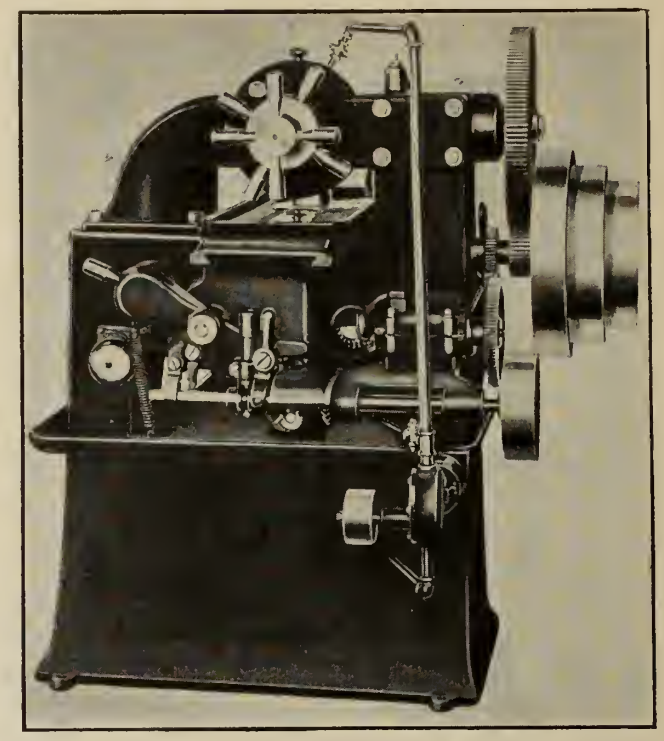

Fig. 2—Rear View of the Automatic Gear Cutter.

This machine is provided with 8 feeds, gear-driven, and is equipped with a friction device reducing to a minimum the possibility of stripping gears through careless handling. Machine also has micrometer index dials reading to

positively at either end of feed traverse, whether dials are set or not. The machine may be fitted with either plain table or chuck and has an extreme swing of 36½ inches.

ferent from the European machines for generating gear teeth and is the result of the combined effort of John J. Grant and Earnest J. Lees.

The machine is designed to automatically cut gears up to 20 inches in dia-

.001 inch on all feed screws, by means of which the tool in the turret may be moved .001 inch or more in any direc-

This boring and turning mill is manufactured by the Gisholt Machine Co., Madison, Wis.

meter. It will cut spur and spiral gears up to 5 inches pitch and worm gears, any pitch up to ¾-inch. It will cut spur,

worm, spiral and helical gears with only a slight adjustment of machine for each gear. It is specially used in cutting cream separator, gas engine gears and helical gears. The use of a hob necessitates a continuous cut. Only one hob is necessary for each pitch for spur gears. By means of a special hob both spiral and spur gears can be cut with one hob. It is only necessary to machine the face of the blank to 1-32-inch of exact size as the bottom of the tooth of the hob will cut the blank to the exact diameter automatically determined by a micrometer stop.

Cutting the Gears.

As shown in Fig. 5, the hob is set at an angle in cutting spur gears. The blank revolving at the proper ratio, automatically feeds vertically through the teeth of the hob and the gear is cut in one continuous operation. When the gears are cut the quick return automatically brings them to their original position and a gong summons the operator to replace the finished gears with blanks. The arbor will accommodate a gang of gears or gear with six inches face. The cone gives cutting speeds of 29, 52 and 84 feet per minute. The vertical speeds are determined by material and pitch required. For spiral gears the hob is set at the angle desired as shown in Fig. 4 and the blanks are rotated to give the correct increase or decrease per revolution to generate the correct angle. No indexing is required and the process is one continuous cut. The hob used is a patented diametral pitch hob, the same used to cut spur gears. To cut a worm gear the hob is set horizontally as shown in Fig. 3. The blanks revolve automatically and feed horizontally into the hob, until the proper centre distances are obtained. No nicking of the blank is required.

Figs. 1 and 2 show the front and rear views, respectively, giving an idea of the general construction and the manner in which the driving motion is conveyed to the hob, giving a powerful drive and still allowing it to be swiveled at any angle. Fig. 6 shows the milling of a plain gear. In this illustration is shown an ingenuous rest used for large gears. By this mechanism the rest takes the thrust immediately under the cut and moves simultaneously with the main spindle.

The machine weighs 2,600 pounds and occupies a floor space of 4 feet by 4 feet 6 inches. The complete equipment includes a full set of change gears, countershaft and wrenches. As an extra an oil pump is attached. The automatic gear cutter is manufactured by the Grant-Lees Machine Company, Cleveland, Ohio.

THE GAS ENGINE AS A SOURCE OF POWER.

At a meeting of the International Association of Stationary Engineers, held in the Temple Building, Toronto, Mr. W. S. Haggas, of the Canada Gas. Power & Launches Company, Limited, illustrated and explained the modern types of gas engines and suction gas producers.

In taking up the cost of producing electrical power by means of large gas engines operating on suction or blast furnace, gas as compared with steam power, he stated that in order to produce, say, 100 electrical horse-power per hour the Carliss engine, belted to the generator, would require at least 400 pounds of coal per hour. The compound condensing engine on the steam turbine would be doing well if the coal consumption did not exceed 300 pounds per hour. It was, therefore, very gratifying to state that with the modern gas engine and suction gas producer official records had been obtained showing the consumption of coal to be 95 pounds per hour for 100 electrical horse-power, measured at the switchboard, or, allowing 15 per cent. loss from engine to switchboard, a full rate of 783 pounds of dry coal per B. H.P., or, roughly speaking, about ¾ pound per B.H.P. per hour. So that, figuring all possible items of cost, such as labor, oil, water, interest, depreciation, etc., power could be produced at from $14 to $15 per horsepower per year. Figure this out on the flat rate basis to the ordinary consumer, and it should not exceed $5 or $6 per horsepower per year, as it is a well known fact that the average amount of power actually used does not exceed one-third that of the possible amount that may be required occasionally.

Speaking of the flat rate, Mr. Haggas stated that he knew of fully 100 gas engines in Toronto operating on city gas, and could say postively that the average cost for all of these did not exceed $12 per horsepower per year, figuring on the flat rate basis.

Figure this out at a flat rate basis and you have about $8.25 per horsepower per year. As to the satisfactory working of large gas engines, there was abundance of proof. Take, for example the Lackawanna Iron & Steel Company, of Buffalo, N.Y., operating ten two-cylinder gas engines of 1,000 horse-power each for electrical service, 16 engines of the same power for blowing their blast furnaces, also engines for other purposes, making a total of some 42,000 horse-power. This installation constitutes one of the most important power plants in the world.

Catalogues of the Trade

By mentioning Canadian Machinery to show that you are in the trade, a copy of any of these catalogues will be sent by the firm whose addresses is given.

IMPERIAL CHUCKS—Catalogue and price list of chucks for lathes, boring mills, etc., manufactured by Ker & Goodwin, Brantford, Ont.

STEEL SUPPLIES—Catalogue No. 27, from the Cleveland Wire Spring Co., Cleveland, Ohio, well illustrated, describing their steel shop boxes, barrels, waste cans, supply racks and other steel equipments for factories.

ELECTRIC TROLLEY HOIST—Pamphlet from the Northern Engineering Works, Detroit, Mich., showing photographs of a few types of their cranes with descriptions of them.

POWER PUMPS AND PAPER MILL MACHINERY—Catalogue from the Sandusky Foundry and Machine Co., Sandusky, Ohio., well illustrated, giving descriptions and full specifications of their line of pumps.

ALUNDUM—A ten-page treatise on alundum for grinding—Norton Company, Worcester, Mass., U.S.A.

METAL WORKING MACHINERY—Catalogue describing the "American" lathes, planers, shapers, radial drills, etc. The A. R. Williams Machinery Co., Limited, Toronto, agents.

NAVY BULLETIN, NO. 22—A book of information designed for the information of manufacturers of electric motors and motor-driven machinery, describing panels, controllers, repair parts, etc. The Cutter-Hammer Mfg. Co., Milwaukee, Wis., U.S.A.

CROCKER-WHEELER BULLETIN—Issued by the Crocker-Wheeler Company, Ampere, N.J. A full set of up-to-date bulletins, bound in covers describing with illustrations, their generator and motor sets, switch-board equipments and electrical accessories.

ADAMANTINE THREADING TOOLS—Catalogue from the American Tap and Die Co., Greenfield, Mass., illustrating and describing screw, plates, taps and dies, wrenches and pipe cutters. These are made in standard and special sizes and their catalogue covers fully this line of work.

ENGINES.—Catalogue from Belliss & Morcom, Birmingham, England, illustrating and describing their patent self-lubricating, quick revolution engines for electric lighting, power, traction and mill driving. Sectional views are shown, results of tests are given, and the action of the governor is explained with diagrams and cuts. There is also a treatise with diagrams on the effect of superheat on steam and heat consumption, and several views of their engines now in use, showing them direct-connected to generators, and equipped for belt and rope drive. Messrs. Laurie & Lamb, consulting and contracting engineers, 212 Board of Trade Building, Montreal, are the sole agents for these engines in Canada. In three years this firm have installed these engines in ten plants in Canada, totalling 12,925 horse power.

AIR COMPRESSORS AND DRILLS.—The Chicago Pneumatic Tool Co., Fisher Building, or 95 Liberty Street, Chicago, are mailing two new catalogues, each 100 pages, Nos. 23 and 24. No. 23 is devoted exclusively to Franklin Air Compressors and is well illustrated. No. 24 deals with the company's widely known line of pneumatic tools and appliances, including Boyer and Keller hammers, Little Giant drills, sand reamers and hoists. Both books are printed in colors, conveniently indexed and strongly bound, making good volumes for references.

GRINDING AND POLISHING MACHINERY.—Builders' Iron Foundry, Providence, R.I., U.S.A. A catalogue describing their emery grinders, with sizes and materials used in construction, illustrating and explaining special features ; emery wheel dressers for truing solid emery wheels running at high speed ; patent countershafts with self-contained belt shifters ; ring oiling polishing machines and leather and canvas polishing wheels.

HYDRAULIC MACHINERY.—An extensive catalogue issued by the Waterbury Farrel Foundry and Machine Co., Waterbury, Conn., describing and illustrating their makes of hydraulic machinery, used in various industrial operations, such as the manufacture of tubing of all kinds, drawn rods and shafting, cups for tanks, boilers, etc., embossed and stamped coins, punching thick blanks from sheet metal, etc. It is of standard size and very neat throughout.

ELECTRICAL EQUIPMENT.—Bulletins from Canadian Westinghouse Company, Limited, Hamilton, Ontario. No. 1092 describes the Westinghouse Multiple Alternating Arc Lamp ; 1102, direct-current multiple arc lamp ; 1128, small power motors for alternating and direct-current circuits ; 1143, regulating and reversing controllers for direct-current motors ; 1144, mill motors for direct-current service. Full descriptions and illustrations are given of all details. Accompanying these was a book of forty pages, containing an article on the Westinghouse electrical machinery for the operation of Mexican mines, by Charles V. Allen.

UNIVERSAL PROPELLER.—Folder describing the universal propeller, manufactured by R. G. & E. Holland, 13 Oakwood lane, Barnton, Northwich, Chesire, England. This propeller is manufactured both as fixed and reversible, and its construction makes it suitable for all classes of vessels from the small motor boat to the large ocean liner.

STEAM TURBINE BLOWERS.—Bulletin No. 3, from the Kerr Turbine Company, Wellsville, N.Y., describing and illustrating in detail steam turbine blowers, forge and cupola blowers, centrifugal pumps, etc. The Kerr turbine is built on the lines of the Pelton water wheel, which has been so successful. Pressure tables are given and also tables of dimensions and shipping weights.

STEAM AND WATER SPECIALTIES—Catalogue No. 9 from the Golden-Anderson Valve Specialty Co., Pittsburg, Pa., containing descriptions and illustrations of their line of globe and angle valves, traps, locomotive valves, standpipes and automatic float valves.

INDIA OIL STONES—Pamphlet from Norton Emery Wheel Co., Worcester, Mass., describing oil stones for sharpening ordinary tools, such as chisels, planes, etc.

LO—SWING LATHE—A neat volume on good paper, well bound and illustrated, with detailed description of and full instructions for running the lo-swing lathe manufactured by Fitchburg Machine Works, Fitchburg, Mass.

BOOK REVIEWS.

TOOL-MAKING—By E. R. Markham, 200 pages. Illustrated. Published by the American School of Correspondence, Chicago, Ill., U.S.A. Price, $1.50.

This is an exhaustive treatise on how to make tools and should appeal to every tool maker and mechanic. It treats of all tools, dies, milling cutters, gauges, dull jigs, etc., and is a volume of practical information for practical men.

PATTERN-MAKING—By James Ritchey. 150 pages. Illustrated. Published by the American School of Correspondence, Chicago, Ill. Price, $1.00.

For metal workers and pattern-makers this work, by a practical man, is both interesting and instructive. It is a valuable compilation of data on patterns, tools and methods of molding.

FOUNDRY PRACTICE AND EQUIPMENT

Practical Articles for Canadian Foundrymen and News of Associations. Contributions Invited.

VENTILATING A BRASS FOUNDRY*

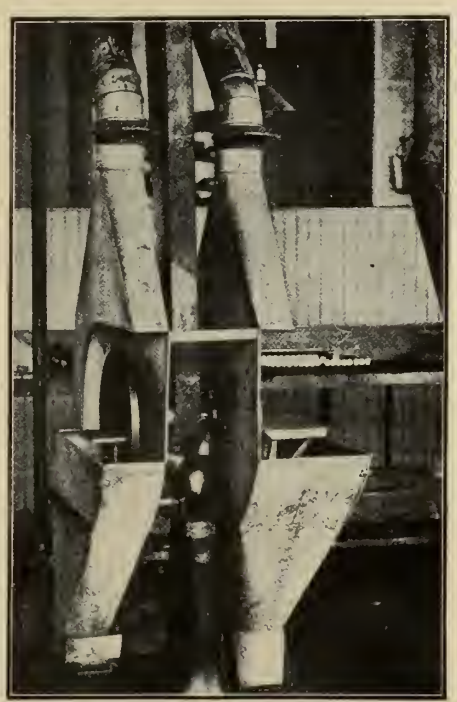
By Walter B. Snow

In much of the early work done for the welfare of the employe there was a strange confusion of motives. Even though the project was primarily humanitarian in its spirit, the advertising department got in its work in proclaiming this spirit to all the world. But out of this confusion has now grown a definite recognition of the purely economic advantages of surrounding the workman with healthful conditions. While some other industries are more directly harmful to the health than is the brass industry, there is, nevertheless, ample opportunity within its field to greatly improve the conditions. Although the heat and fumes are primarily uncomfortable and only secondarily injurious, the greatest harm is done by the dust which is inhaled. This dust is usually of mineral or metallic origin resulting from the grinding, polishing, tumbling, and sand blasting processes, and also from the shaking out of the castings.

Injurious Industries.

It is commonly recognized that life is shortened by working in a dust-laden atmosphere, but the extent to which some industries are injurious is startling. In the cutlery and tool industry, which is declared to be one of the most dangerous of trades in this class, the average age of the operatives at death is exceedingly low and in establishments conducted without proper hygienic precautions sound men are rare after a few years' work. The prevailing cause of death is consumption, which usually overtakes a susceptible worker so early that his period of usefulness does not extend much beyond five or six years, except where the health is properly safeguarded.

The testimony of physicians is, that of those employed in this industry nearly all who reach the age of 40 die of consumption, excepting those who succumb to some acute disease. As proof of this statement, it is instructive to note that in Northampton, Mass., an important seat of the cutlery industry, the death rate from tuberculosis for the entire male adult population was 2.9 per thousand, while that for the cutlers of that town was four times as great; namely, 11.8 per thousand. The trouble lies not so much in any directly poisonous results from inhaling the dust as in its power to bring about constant irritation, which produces such a condition of the mucous surfaces that they more readily admit of invasion by disease germs. Fortunately brass is less irritating than steel, and consequently the results in the brass industry are not as disastrous as they are among the cutlers. But the dust of corundum and emery is peculiarly irritating, and the brass workers' surroundings are therefore susceptible of marked improvement.



Grinding Discs Equipped with Special Hoods Designed to give Freedom to Workmen.

Laws to Safeguard Health.

The unhygienic conditions existing in the various industries have received the attention of State Boards of Health, whose official investigations are bringing about the passage and enforcement of more stringent laws looking to the safeguarding of the health of the employes in all industrial establishments.

In a word, advance has been made from a matter of individual interest to one of almost national importance. The statute books of the leading States already contain laws, usually somewhat vague in their expression, which require cleanliness, light, warmth, ventilation, and the introduction of specific devices for removing dust, fumes, and the like. While the first impulse of the manufacturer may be to resent the enactment of further laws, yet his compliance with them is not without eventual advantage. Not only will a better class of men prefer to work for him if improved conditions are provided, but there will be far less interference with work because of sickness, more energy in the work which is done, and less loss by death of the potential value possessed by the man who has become thoroughly skilled in a given line of work. Continued sickness and death naturally mean constant replacement of individuals, with the loss of knowledge and skill gained by those who have gone. As a result there is far less stability of employment in an unhealthy industry.

Ventilating Appliances.

Experience has shown, and the reports of investigations confirm the fact, that mechanical means are absolutely necessary to maintain a rapid air change or to insure proper removal of dust. In fact, the fan blower figures everywhere as the only device adapted to secure these results. It is manifest that the action must be positive, and of sufficient intensity to create ample movement of air. Where there is but little dust or the requirements of ventilation are slight, a fan applied for mere renewal of air throughout the entire extent of a room will meet the requirements. When warranted by the size of the plant the fan may form part of a blower heating system, by means of which warm air from a centralized heater is delivered under pressure through pipes to all parts of the building. In overheated rooms and particularly for summer ventilation the disc or propeller type of fan meets the requirements if placed in wall or ceiling.

Wherever dust or fumes are formed locally, as in connection with grinding

*A paper read by Walter B. Snow before the American Foundrymen's Association at Philadelphia.

and polishing wheels, tumbling barrels, or furnaces, the exhaust should be direct from hoods which enclose the objectionable source as completely as possible. In a word, prevention is better than cure. The objection which is often shown by workmen to hoods and similar contrivances—even to the extent of actual destruction—is largely due to their improper construction. In fact, the cause for condemnation or criticism of many exhausting systems lies in the method of application of the fan, and not in the fan itself. The success of the fan not only depends upon its speed and its proper proportioning to the work, but also upon the system of piping and hoods which would give the greatest efficiency. It seems so simple to employ a local tinsmith to rig up an exhausting system that it is not strange that unsatisfactory conditions result.

It is far better policy to secure the best advice, which will always be freely given by blower manufacturers, and then have the thing done right. It must not be overlooked that the installation of an economical exhausting arrangement requires definite engineering ability, and should only be undertaken by one who makes a specialty of this particular class of work.

Cost of Installation.

Because of the lower first cost the user is always strongly tempted to buy the smallest apparatus that can be made to do the work. But first cost is only one of the factors in the total cost. Large slow running fans with ample pipe areas are conducive to small power expenditures. It is easy to save enough in power in six months to pay the additional cost of a more efficient outfit or system. Thereafter its economy is all clear gain.

Even though the fan be of ample size when first installed, it may, as a result of speeding up to meet added requirements, frequently demand from 50 to 100 per cent. more power than would be necessary to do the work with a proper outfit. It is none too generally understood that the power required to drive a fan increases as the cube of the speed. In other words, that doubling the speed calls for an eight-fold increase in power, while 27 times the power is required at three times the speed; an increase of only 25 per cent. in speed calls for nearly double the power, and yet such an increase is common enough. How long would it take to pay for a new outfit from the money thus squandered in excessive power?

The designs of hoods for grinding, polishing, or buffing wheels are many and varied. Each must be arranged to suit the particular class of work for which the wheel is used. In some cases it is even necessary to have several different types in the same room. This is true where the pieces of such shape and size that it is impossible to get very close to the wheel, the result being that at one time the operator uses the wheel at a point near the top, and again at a point directly underneath. Under these conditions especial care must be taken to provide the most effective type of hood and maintain the maximum blast. In heavy work of this type the air suction pipe should be five inches in diameter for wheels up to and including 16 inches in diameter by three-inch face. In ordinary grinding and buffing rooms the suction pipes should be four inches in diameter for wheels 2½ inches or less in width, and from 10 to 18 inches in diameter. Wheels ranging from 19 inches to 28 inches should have 5-inch or 6-inch pipes according to class of work for which they are used.

All hoods should be so designed that the velocity through the openings should not be less than 5,000 feet per minute, which is usually sufficient to create the draft necessary to carry away the particles. The best general type of hood is of patented form, provided with a receptacle below to trap out all heavy particles, as well as the threads from the buffing wheels, while allowing the finer dust to pass through the pipe. The result is that the metallic particles are left in clean condition ready for resmelting, and the wear on the pipes and the fan is greatly reduced. This arrangement also prevents the annoyance caused by the dust from the rag wheel adhering to the fan wheel and throwing it out of balance. The trapping-out feature furthermore permits of the ready recovery from the bottom of the hood of any small piece of work or other material, which with other types of hoods might get into the main trunk line or up into the fan.

All properly designed systems should have clean-cut caps so as to provide free access to the interior of the piping for the removal of anything that might possibly tend to clog it. The main suction pipe should be proportionately increased in size as each connection is made to it.

Fan Installation.

To secure the most economical results a fan should be chosen which has an area of inlet about twice the combined area of the inlet pipes. This proportion will give the maximum velocity through the branch pipes and hoods. The fan should then be operated at about 1½-ounce speed, under which condition it would consume about ½-horse-power for each 4-inch opening.

The most work is done, and consequently the most power is required by a fan when it is discharging with free inlet and outlet. The more extended the system of piping, the smaller the area of inlet or outlet; and the greater the friction, the less will be the volume delivered by the fan; and consequently the less will be the power required to drive it. It is therefore manifest that the fact that the fan is consuming but little power is not always evidence of its successful operation, for it may be doing little effective work.

The dust which is collected by the fan should be discharged into a centrifugal dust collector. Here the dust is separated from the air by centrifugal force; the air escapes from the top practically free from dust, while the dust itself drops out of the bottom through a pipe. It should be periodically removed. The dust from wheels grinding iron and steel should not be mixed with that from rag wheels, for in some cases fire will result. Separate fans and systems should be used.

Exhausting From Tumbling Barrels.

The same general principles hold in connection with systems exhausting from tumbling barrels. If a maximum effect of the fan is desired on tumbling barrels equipped with hollow trunnions, the area of fan inlet should be about double that of the sum of the openings in the trunnions. The sizes of pipes and the speeds of fans to be applied in connection with housed rattlers must depend largely upon the conditions, but a 6-inch pipe connection will usually serve for each tumbling barrel, if the same is tightly enclosed. A fan running at about one ounce speed will give sufficient draft.

No general rules can be given for the application of the fan system to sand-blast rooms or apparatus. The arrangement must depend entirely upon the local conditions, but the provisions must be generous if successful results are to be obtained.

With installations such as are here described it is possible to maintain a relatively healthy atmosphere, which is bound to insure better work.

PATTERN MAKING FOR THE FOUNDRY*

Showing the Several Operations in the Construction of a Pattern

BY JAMES RITCHIE

A good example of the manner in which patterns are built and glued up is shown in the construction of the pattern for the 6-inch sheave pulley shown in Fig. 1. The groove is a semi-circle ½-inch wide, and the rim containing the groove is connected with the hub by a solid web ¼-inch in thickness, and having four or six holes, each 1-inch in diameter, this web taking the place of arms. If there is to be no finish on the sheave, as is usual, the only allowance to be made on the pattern, which must be parted, will be for shrinkage and for draft. A cross-section through the finished pattern for this casting is shown in Fig. 2.

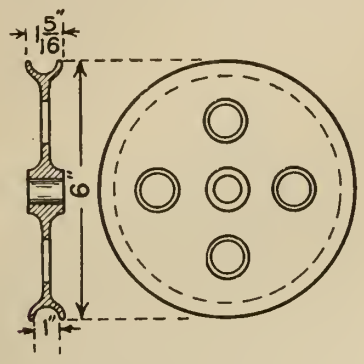


Fig. 1—Sheave Pulley.

In all large patterns of this kind, the web is first glued up in sectors, six, eight or more in number, according to the size of the sheave (see Fig. 3). The sectors are fitted by hand or on the trimmer, the ends are glue-sized, and when the sizing is dry the joints are carefully scraped smooth, and the whole glued together. After drying four or five hours, it is sawed to a circle of ½-inch greater diameter than the finished pattern, and the block for the hub is glued over the centre. Six segments to form the outer rim are glued around the outer edge, care being taken to break joints as shown in Fig. 3. If the groove is to be large, the six segments of like thickness are glued over the first, breaking joints not only with the first set, but also with sectors of the web. In other words, in all glued-up rims, no two joints should be directly over each other. All joints must be so broken and so distributed as to give the greatest possible strength to the rim. In the present case, our pattern is so small that it is only necessary to use a thin board, ¼-inch in thickness, for each half of the web. After sawing to 6½ inches in diameter, ½-inch for turning, a block ½-inch in thickness is glued on the centre of each to form the hub; and six segments, 1¼ inches wide and ½-inch in thickness, are glued around on the outer surface of each to form the rim and groove, as shown in Fig. 4.

Care must be taken to place the segments so that the grain of the web will be crossed by two of the segments as shown in the drawings. On the second half of the pattern, a thin circular block ¼-inch in thickness, is glued on the inside opposite to the hub block, to form the projection (⅛-inch) which will keep the two halves of the pattern in alignment, as shown in the cross-sectional drawing in Fig. 2. Having glued up the stock as described, and as shown in Fig. 4, the outside must be planed to a level surface, or so that the six segments forming the rim and the centre hub block will be in the same plane.

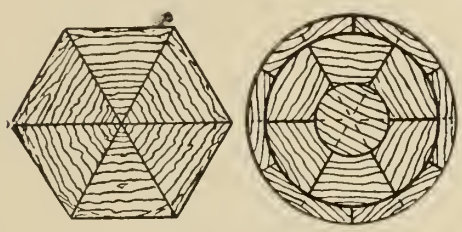

Fig. 3—The Sectors.

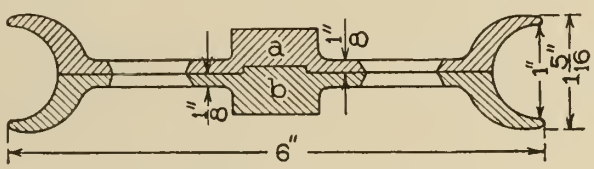

Fig. 2—Cross Section of Pattern.

Turning the Pattern.

The half pattern is now screwed on the screw chuck of the lathe as illustrated in Fig. 5, and the inside, or the parting face C, is turned perfectly straight and true. The edge is turned down to 6 inches in diameter, and the quartered circle shown by the dotted lines is carefully shaped. A template, made as shown at D, will assist greatly at this stage of the work. A recess is turned at the centre, and in the face of A, Fig. 2, 1½ inches in diameter and ⅛-inch deep, to receive the corresponding projection of the half pattern B which is to keep the two halves in alignment. The half pattern A, is now removed from the screw chuck, and the second half, B, is screwed on and turned in the same manner except that the central projection is carefully turned to fit in the recess in A. Before removing B from the chuck, test by trying the second half A, and change B until a perfect fit is obtained between the two halves, not only in the central recess and projection, but also in the two curves which form the semi-circular groove of the rim. A cross-section of the pattern at this stage of construction is shown in Fig. 6.

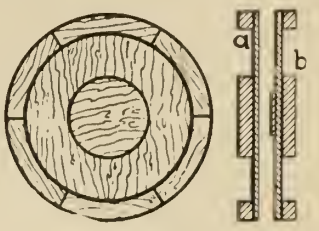

Fig. 4—Making Rim.

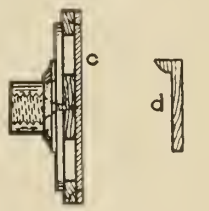

Fig. 5—Fastening Pattern for Turning.

A disc or chuck of wood 5½ inches in diameter is now screwed to the iron face-plate, or the screw chuck, and turned off true on the face with a projection ½-inch high, which will fit into the recess in the middle of the parting face of A. This projection will centre the half pattern A on the face-plate, and it can be held in position by two

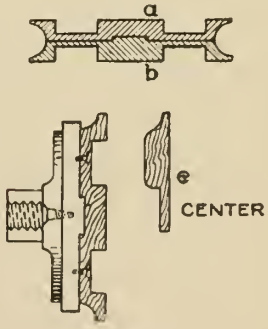

Fig. 6—Section and Pattern Fastened on Chuck.

* Copyrighted and reprinted by permission from the instruction paper on Pattern Making, in the home study course of the American School of Correspondence, Chicago.

or four short wood screws driven through the web into the wooden chuck, as shown in Fig. 6. Care must be taken to place the screws in such a position that the screw holes will be cut or bored out when making the four or six openings 1-inch in diameter in the finished web of the pulley. The screws must be small and slender and the heads well countersunk out of reach of the turning tools. The face of the half pattern is now turned to the required shape, the tem-

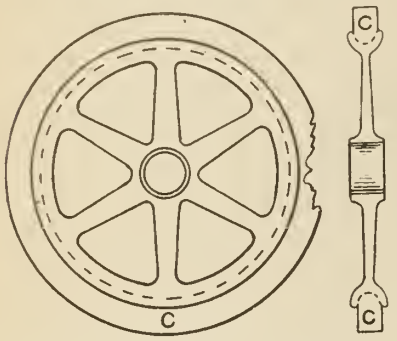

Fig. 7—Periphery Core Print.

plate shown at E in Fig. 6 being used for the purpose. Having finished with fine sandpaper, remove the half pattern and turn off the projection on the centre of the wooden chuck; turn a recess instead to receive the projection on b, and proceed with this second half as with the first. If the wood has been well seasoned, and the work carefully done a perfect 6-inch sheave pulley will be obtained, such as shown in Fig. 2.

Completing the Operations.

The pattern for a sheave pulley has been explained because it embraces so many profitable points and conditions, not only in gluing and building up, but especially in chucking and turning, all of which must be done with great care and accuracy. The 1 inch holes in the web are bored out with a 1 inch center bit, which, when well sharpened, will not split or splinter the thin webs of the two halves of the pattern, if care is taken

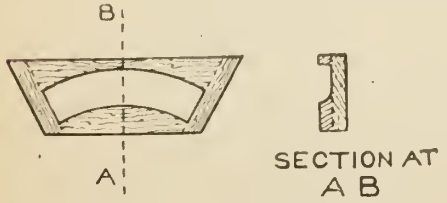

Fig. 8—Core Box.

to reverse the bore from the opposite side when the points of the center bit come through. The holes should be given a slight draft as shown in Fig. 2, with a small half-round cabinet file. When very large sheave pulleys, having arms, are to be made, such as are common for power transmission by rope or cable, the patterns are not halved but are made in one piece, and the groove is cored around the rim. Such a pattern is illustrated in Fig. 7, with a wide core print c c extending entirely around the periphery of the pattern.

A segmental core box is made for one sixth or one eighth the circumference of the wheel, as shown in Fig. 8, and here again only half of the core box for a full core is needed. When coring the rim as above, the core print must be made wide, at least two to three times the depth of the groove, so that the core may rest firmly and remain in position without tilting while the metal is being ponred into the mould.

NEW PROCESS FOR MALLEABLE IRON AND STEEL.

Two Australians have evolved a process for directly converting iron ore into malleable iron or steel by a continuous system. It is claimed that the new discovery will effect a saving of 25 per cent. in the manufacture. The ore is simply concentrated by ordinary methods, or if it is magnetic it is separated electrically until the pure oxide of iron is obtained. The oxide of iron is passed through a revolving cylinder heated by waste gases from subsequent operations, and brought in that cylinder to a dull red heat. It drops from the cylinder to a second similar cylinder, and in the latter it is brought into contact with the deoxidizing gas, which is forced through and brought into contact with the heated ore. The heated ore is thus converted into a pure iron. Accompanied by and protected by the deoxidizing gas, it is passed into a third chamber or melting hearth, where it falls into a bath of molten iron, and is converted directly into steel or balled up as malleable iron.

ENTERPRISE CLUB.

The Enterprise Club, that is the name of an organization recently formed by the men of the Enterprise Foundry, of Sackville, N.B. The foundry company has always taken much interest in its employes and the club has been formed largely the result of that interest. The club rooms, three in number, are in the Enterprise office building. One is fitted up as a reading room, with current magazines and papers; another is a smoking room, while the third will be the lecture room. In the last, lectures will be given every fortnight.

DOMINION STEEL.

As yet the Steel people say there is no great falling off in orders. The two leading Canadian railways have still ample funds and steel rails are in demand.

UTILITY OF FAN BLOWERS.

With the possible exception of the steam pump, writes Walter B. Snow, it is doubtful if any other mechanical device has so varied a field of direct application as the fan blower; these two machines really being in the same class, the one handling liquids at pressures measured in pounds, while the other creates movement of air and gases under pressure, differences measured in ounces.

Fan blower applications may be broadly divided into two classes. First, those in which the object is to actually transport the air or gas, and second, those in which the air serves as a medium for the transportation of other materials. Ventilation and the supply of air for combustion are properly included under the first classification. The conveyance of light material and the transmission of heat or moisture in the air come within the second classification.

Ventilation whether secured by natural or artificial means results only from the creation of a pressure difference between two points such as to cause a flow of the liquid from the higher and the lower pressure area. In the case of natural ventilating systems maximum efficiency is secured only through the employment of flues and ducts of large area, through which the air flows at low velocity. At best, the mechanical efficiency of the heater flue is very low. With a fan, however, much greater pressure difference can easily be created and smaller pipes with higher air velocities employed. With the fan; the heat expenditure necessary to produce a given air movement is surprisingly less than with natural draft in a flue or chimney.

According to the degree of activity of the occupant the velocity of the air admitted to the room may be high or low, but it is easily regulated where a fan is employed. In the sparsely-occupied building the per capita space is large, the air volume therefor required is relatively small, and the rate of flow may be high. In the crowded hall of audience the minimum of floor space is provided for each occupant and the maximum of air supply is required. Here the utmost refinement is necessary in the tempering and distribution of the air.

In the ordinary building, ventilation is very properly a process of substitution of fresh air for foul air, but the fan does not absolutely control the conditions, for the walls are usually porous and there are leaks around the windows and doors. In the mine, however, with its practically air-tight chambers and its vertical shaft, there is no appreciable inward or outward leakage. All air which passes through the mine likewise passes through the fan, very positive control being had over its distribution.

The De La Vergne Oil Engine

An oil engine specially designed for the use of ordinary kerosene or fuel oil known as the De la Vergne Oil Engine, has been placed on the market and a number of them have been operating satisfactorily for many months. In Fig. 1, we show a fifteen brake horse power De la Vergne Oil Engine, direct connected to a ten kilowatt generator. Fig. 2 is a twin cylinder engine of the De la Vergne type, with one-half in section. Air port A and exhaust port E are in the middle of the cylinder, indicating at once that the engine operates on the two-stroke cycle and is single acting; hence in a twin cylinder engine, the crankshaft receives in each revolution two impulses, the result being a uniform turning moment.

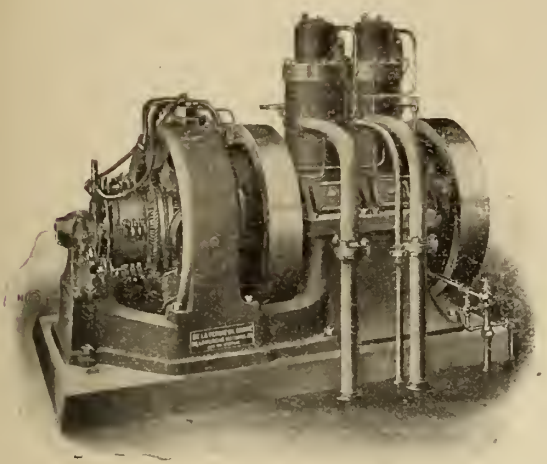

Fig. 1—A Twin Cylinder 15-h.p. De La Vergne Direct Connected to a 10-k.w. Electric Generator.

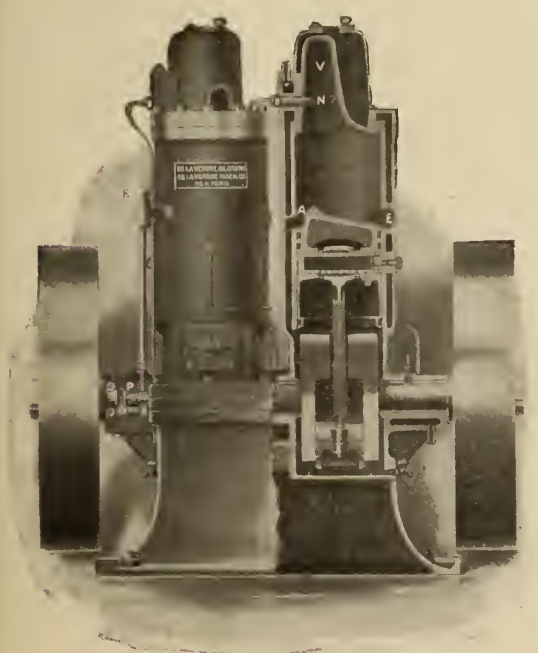

Fig. 2—A Twin Cylinder with one-half in Section.

There are no batteries sparking dynamo, carbureter, or mixing valve. The cylinder head V (Fig. 2) is shaped as a bulb, kept hot enough by successive explosions to ignite the combustible mixture. This bulb or vaporizer is made of gun iron, heated up at the start by a kerosene blow lamp.

Pre-ignitions cannot occur for on the up-stroke, there is nothing but pure air in the cylinder which has entered under slight pressure from the enclosed crank case through port A. Just as the piston is reversing its motion, oil is sprayed into vaporizer V by nozzle N. The heat of the walls of the vaporizer and the hot air resulting from the high compression, at once vaporize the oil and burn it rapidly, thus giving the descending piston an impulse. Just before the end of the down stroke, exhaust port E is uncovered by the piston to let the burnt gases escape to the atmosphere. No exhaust valve is required.

A small plunger pump forces the oil into the vaporizer suddenly, at the right time and in proper quantity to suit the load on the engine. This pump is under the control of an ingenious and simple throttling governor, fastened to and revolving with the flywheel. This arrangement is shown in Fig. 3. A frame F is fastened with two studs, concentrically, to the inside of the flywheel. To this frame is hinged the cam ring R, which, on the flywheel side, has a projection B, and back of that cam projection C, raising the roller A once each revolution of the flywheel, thus moving the oil plunger P. The stroke imparted to the pump plunger is gauged by the lever L, pivoted to frame F. L has a wedge W, which separates the cam ring from frame F. When the engine is started, the governor does not come into action until the normal speed is approched. Under light load, the speed will increase, when by the action of centrifugal force, the counterweight K will overcome the tension of spring S, thus withdrawing wedge W. Spring E always keeps roller A in contact with cam ring R, and when the wedge is withdrawn, buffer G cannot actuate the pump plunger and no oil will be injected. Knob K' at the head of the throttle bar T is used at the start for pumping oil by hand. Lockout N serves to limit the stroke of the oil pump.

The two concentric slots in frame F allow adjustment when it is desired to greatly change the normal speed of the engine. For smaller speed variations the spring S and weight K can be shifted in the holes of lever L. The close regulation obtained with this governor and the high rotative speed make this engine admirably suited to electric work.

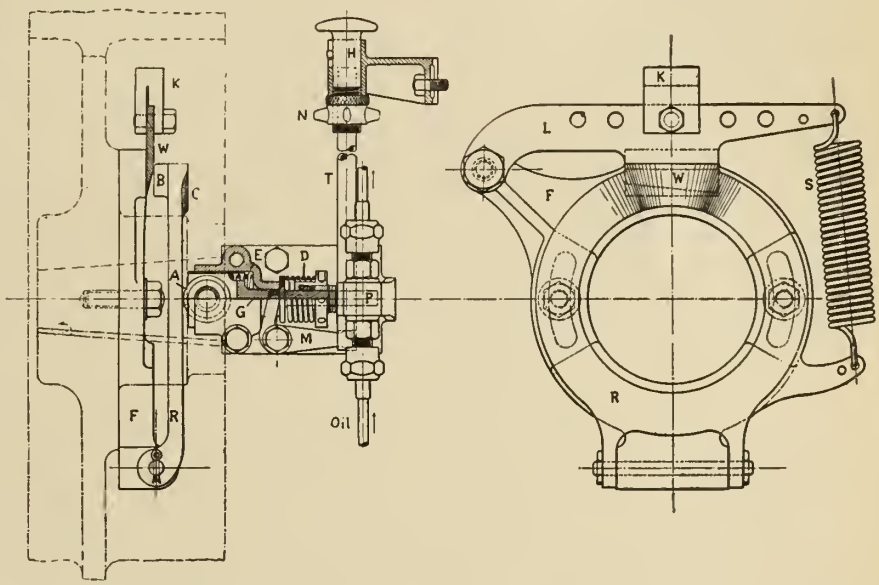

Fig. 3—Details of the Governor and Fuel Pump.

The steel oil spray nozzle is so arranged that it very rarely requires cleaning out, deep grooves being cut helically into the spray pin. The pressure under which the oil is forced in keeps these grooves clean. A steel ball check valve prevents the explosion from firing back into the oil pipe. The entire nozzle is inserted in a section of the vaporizer, which is cooled by circulating water. A small rotary pump driven by spur gear on the shaft circulates the water first through the crank case and around the three bearings, then

through the two cylinders and around the spray nozzle.

A 15 h.p. complete weighs 1,180 lbs., and a 7½ h.p. weighs 750 lbs., with cylinder 7 inch x 7½ inch running at 450 R.P.M. This engine is manufactured by the De la Vergne Machine Co., New York City.

PERSONALS.

R. A. Brown, Calgary, has been appointed city electrician of Nelson, B.C.

H. C. Philpott, general sales agent of the Dominion Car and Foundry Co., of Montreal, died suddenly of heart failure on Nov. 21st.

G. G. S. Lindsay has been elected president of the Crow's Nest Pass Coal Company, and James D. Hurd succeeds him as general manager.

Geo. A. Gallinger has been appointed manager of the Pittsburg, Pa., office of the Independent Pneumatic Tool Co., at 1210 Farmers' Bank building, Pittsburg.

Alan Owen Leach, of Toronto, has just finished an appraisal of the Great Northern Railway, and is at present on a tour of inspection of that road with the general manager, Louis J. Hill.

J. C. Boyd, superintendent of the Canadian Soo canal. is being transferred to the Williamsburg canal, with headquarters at Morrisburg. J. L. Ross, C.E., Morrisburg, will take Mr. Boyd's place at the Soo.

Albert Elsstrom, manager of the Gothenberg plant of the General Electric Company of Sweden, is in Canada on business. Kilmer & Pullen, Toronto, are the representatives of this company in Canada.

AWARDED GOLD MEDAL.

J. W. Cumming, manufacturer of modern patented coal and plaster drills, high grade miners' tools, mine cars and hitchings, New Glasgow, N.S., has been awarded the gold medal at the Halifax Provincial Exposition, 1906 and 1907.

BOOK REVIEW.

THE BLACKSMITH'S GUIDE—By J. Sallows, published by The Technical Press, Brattleboro, Vt., U.S.A. 150 pages. Price, $1.50. It is a book of six chapters treating in a very practical way with illustrations, machine forging, tool forging hardening and tempering, high-speed steel, casehardening and coloring, brazing and general blacksmithing. On every page is valuable information for foremen and blacksmiths.

SOCIETY OFFICERS.

Canadian Mining Institute.

President, George R. Smith, Thetford Mines, Quebec; secretary, H. Mortimer Lamb, Victoria, B.C.; treasurer, J. Stevenson Brown, Montreal.

Toronto Branch A. I. E. E.

Chairman, R. G. Black; vice-chairman, K. L. Aitken, secretary, R. T. McKeen.

National Association of Marine Engineers of Canada.

Grand president, Alex. L. De Martigny, Varennes, P.Q.; grand secretary, Neil J. Morrison, St. John, N.B.

Canadian Electrical Association.

President, R. S. Kelsch, Montreal; 1st Vice-Pres., W. N. Ryerson, Niagara Falls; 2nd Vice-Pres., R. M. Wilson, Montreal; Sec.-Treas., T. S. Young, Toronto.

Canadian Association of Stationary Engineers.

President, W. A. Sweet, Hamilton, Ont.; Vice-Pres. Jos. Ironsides, Hamilton, Ont.; Secretary, W. Outhwaite, Toronto, Ont; Treasurer, J. M. Dixon, Toronto Ont.

Canadian Railway Club.

President, W. D. Robb; secretary, James Powell, chief draughtsman motive power department, G. T. R., treasurer, S. S. Underwood, chief draughtsman car department, G. T. R.

Engineers' Club of Toronto.

President, C. B. Smith; secretary, C. M. Canniff, 100 King Street W.; treasurer, John S. Fielding, 15 Toronto Street.

Canadian Society of Civil Engineers.

President, W. McLean Walbank; secretary-treasurer, C. H. McLeod. Rooms, 877 Dorchester street, Montreal.

Society of Chemical Industry.

Chairman, Prof. W. H. Ellis; vice-chairmen, H. H. Van Der Linde, Milton, and H. Hersey and A. McGill; hon.-secy., Alfred Burton, 44 York Street, Toronto.

Ontario Land Surveyors.

President, Thos. Fawcett, Niagara Falls; vice-pres., A. J. Van Nostrand, Toronto; secy.-treas., Capt. Killaly Gamble, Toronto.

The Canadian Clay Products Manufacturers, in convention in Ottawa last month, passed a resolution asking the Dominion and Provincial Governments to make appropriations for the technical training of students in the development of non-metallic minerals, which would include the manufacture of different kinds of brick, tile, pottery, porcelain, glass, cements plaster of Paris, etc. The development was hampered by lack of investigation into the possibilities of these minerals, and lack of the technical knowledge necessary to the progressive development of the clays, shales and marls. These resources were more important than any other mineral owing to their intimate association with Canadian domestic and social needs. A technical school devoted to these subjects, said the resolution, would encourage individual enterprises in the utilization of these resources and do away with the necessity of importing foreign goods and foreign skilled labor.

UNIVERSITY ENGINEERING SOCIETY.

J. H. Hall, representative of the Railway Union at Ottawa, spoke to the members of Toronto University Engineering Society on "Railway Accidents," in which he defended the conductors. He recommended the students to go into railroad work, where there are great opportunities for young men in Canada. He said the block system should prevail on the railways, and there is no reason why it should not be on the double-track systems.

SELLING MAGAZINE ANNIVERSARY.

The first number of volume four of Selling Magazine marks another milestone of this successful journal. This special November issue contains a fund of information for sales and publicity men. The special feature of the magazine is a directory of technical, trade and class publications, giving size of page, rate per page and circulation of trade journals which may be employed in advertising machinery, tools, industrial equipment and supplies.

TO KEEP TOOLS FROM RUSTING.

Take two ounces of tallow and one ounce of resin; melt together and strain, while hot, to remove the specks which are in the resin. Apply a slight coat on the tools with a brush and it will keep off the rust for any length of time.—Practical Carpenter.

CHEAP POWER.

At a cost of $45,000 the town of Gravenhurst has installed a power plant at South Falls, a picturesque spot eight miles distant from the town. Situated on the south bank of the Muskoka river, the power building is a substantial brick structure with concrete foundations and floor. The electrical equipment was built by Allis-Chalmers-Bullock, Limited, of Montreal, and includes a 450 k. w., 60-cycle. 3-phase, 6,600 volt water wheel type, alternating current generator, running at 600 r.p.m., with a 15 k. w. direst current generator as an exciter; two 250 k.w. transformers, and the generating station switchboard, instruments and other auxiliary apparatus. The generator is directly connected with and driven by a horizontal water wheel, made of bronze, with a capacity of 750 horse-power. The plant is so constructed that the capacity can be doubled at a cost of about $20,000, and it has been estimated that the flow of the Muskoka at South Falls is such that during low water it is possible to generate 4,000 horse-power. The water wheel was installed by the Jenkes Machine Co., Sherbrooke, P.Q. At the banquet celebrating the opening of the new power plant, T. T. Simpson, consulting engineer, of Ottawa, who had charge of the work, stated that the cost to the town of developing the power worked out at $7 per horse-power per annum.

INDUSTRIAL PROGRESS

CANADIAN MACHINERY AND MANUFACTURING NEWS will be pleased to receive from any authoritative source industrial news of any sort, the formation or incorporation of companies, establishment or enlargement of mills, factories or foundries, railway or mining news, etc. All such correspondence will be treated as confidential when desired.

New Plants and Additions.

Tolton Bros. will erect a box factory at Guelph.

Mossy River, Man., will erect a bridge near Winnipegosis.

T. E. Essery, Toronto, will erect a brick factory to cost $20,000.

The Paris Plow Co., Paris, Ont., will erect a warehouse to cost $9,000.

Mathew & McNaughton, Calgary, will erect a machine shop to cost $6,000.

The Raven Lake Portland Cement Company has gone into liquidation.

R. Beach, Winchester, Ont., will establish a mattress factory in that town.

A brick plant will be erected at Claysmore Siding, Alta., to cost $25,000.

Messrs. McKeough & Trotter, Chatham, Ont., are erecting a machine shop.

The Western Fire Clay Products will erect a plant near Yellow Grass, Sask.

Rider & Kitchener's sawmill at Lindsay, Ont., was destroyed by fire recently.

The Peterboro Lock Co., Peterboro, will erect an addition to present premises.

The Winnipeg Power Committee have decided to erect a bridge to cost $40,000.

The Ridgetown, Ont., carriage works suffered loss by fire to the extent of $800.

The waterworks and lighting plant for Carman, Man., were completed recently.

The repairs necessary on the electric light plant, Wingham, Ont., will cost $10,000.

The Shuttleworth Chemical Company, Toronto, will erect a building to cost $25,000.

The Aluminum Crown Stopper Company, Toronto, will erect a factory to cost $30,000.

Shurly & Dietrich, Galt, will erect a building and plant for the tempering of steel saws.

The main building of Kreutziger's planing mill, Waterloo, Ont., was destroyed by fire.

The Eagle Spinning Co., Hamilton, will erect an addition to its works at a cost of $50,000.

A large lumber mill will be erected at Prince Rupert, B.C., by G. Brown, of San Francisco.

The Edmonton Produce Co., Edmonton, Alta., will erect a cold storage plant to cost $50,000.

The foundry in connection with the Stevenson Boiler Works, Petrolea, was destroyed by fire.

Dickson Bros., Camphellford, Ont., will build the Riverdale park footbridge, Toronto, for $3,421.

The Albert Biscuit Company, Calgary, are considering the erection of a factory in Edmonton.

Fire in the plant of the Diamond Glass Works, Montreal, did damage estimated at $6,000.

The large tannery of E. Julien at Limoilou, Que., was destroyed by fire, the loss being $15,000.

The Atikokan Blast Furnace recently shipped 2,000 tons of pig iron to Sault Ste. Marie, Ont.

Rapid progress is being made with the plant of the Electric Smelting Company at Welland, Ont.

The Grand Trunk Railway has laid off 250 hands from its shops at Point St. Charles, Que.

The American-Abell Engine Company, Toronto, will establish a warehouse in Calgary, Alta.

The sawmill of J. Stormont, West Lorne, Ont., was destroyed by fire, with a loss of $3,000.

Ex-Ald. Armstrong, London, Ont., announces that he will erect a new brass works in East London.

The Century Telephone Company will transfer its Canadian branch from Toronto to Bridgeburg, Ont.

The Rideau Foundry & Malleable Castings Company, Smith's Falls, Ont., recently opened their new plant.

A Montreal syndicate has secured possession of the St. Lawrence Power Company's big plant at Cornwall.

The Wahesso Cotton Company, Three Rivers, Que., is going on rapidly with the construction of its new plant.

The plant of Blakeney & Company, Hull, Que., was completely destroyed by fire, entailing a loss of $8,000.

The planing mills of R. Leeder & Sons, Toronto, were destroyed by fire, causing a loss of more than $20,000.

The Union Foundry and Machine Works, West St. John, N.B., are making extensive improvements to their plant.

The stave and heading mill, owned by J. Greenless and M. Kennedy, at Forest, Ont., was destroyed by fire, loss $3,000.

The Cleveland Cobalt Company have under consideration the question of establishing an electric plant at Cobalt, Ont.

The factory of the Seaman Kent Co., Meaford, Ont., manufacturers of hardwood flooring, was totally destroyed by fire.

New telephone buildings are to be erected in Charlottetown, P.E.I., and a power plant and a complete equipment installed.

The Intercolonial freight sheds were destroyed by fire, at Campbellton, N.B., Nov. 1st, with a total loss of about $30,000.

The Dominion Power and Transmission Company will erect a new freight shed and large car shops at Hamilton in the spring.

The Granby smelter, at Greenwood, B.C., with the entire blast of eight furnaces, is closed on account of the low price of copper.

Frank H. Fleer Company, Toronto, will erect two reinforced concrete gum factories on Sterling road, in that city, at a cost of $65,000.

The new power house for the Montreal Street Railway at the corner of Notre Dame street east and Raymond street, is nearing completion.

The Victoria Machinery Depot, Victoria, B. C., has been awarded the contract for repairing the C.P.R. steamer Tartar, the price being $10,000.

The Kauffman Rubber Company, recently formed in Berlin, elected the following officers recently: President, J. Kauffman; secretary, A. R. Kauffman.

The Robb Engineering Company has been awarded the contract for placing three new boilers in the wheel house of the Montreal waterworks.

The warehouses of the Singer Sewing Machine Company and the Pioneer Fruit Company, Brandon, Man., were damaged by fire to the extent of $10,000.

The Western Fuel Company, of Nanaimo, B. C., have recently purchased a 220 kw. d.c. C. G. E. generator, direct connected to a Robb-Armstrong engine.

G. Walter Green has just added to his plant in Peterboro, a warehouse 40x75 feet, and a new machine shop 35x120 feet, which is being equipped with up-to-date machinery.

The electric furnaces at the plant of the Electro-Metals, Limited, at Welland, Ont., were recently put into operation, and the results are said to have been very satisfactory.

Ernest Scott has started a machine shop at 91 Bleury street, Montreal. He has installed considerable machinery and is making a specialty of die-making and experimental work.

Fire did damage to the premises of the Toronto Electric Light Company to the extent of $5,000. The blacksmith shop was destroyed, along with the stables and a storehouse.

The Britannia Copper Company, at Howe Sound, have recently installed two 30 h.p. 850 r.p.m. Allis-Chalmers-Bullock induction motors for the operation of their conveyor systems.

A seventy-five horse-power Horashy-Stockport gas engine has been installed in the premises of the Queen City Printing Ink Company, Toronto, by the Colonial Engineering Co.

The Assessment Commissioner, Toronto, has recommended that the city lease the Don Foundry Company, 120 feet of land on Ashbridge's Bay, at $150 per year, and taxes for 21 years.

It has been announced by the Canadian Pacific Railway that a substantial reduction will take place in freight rates between eastern Canada and points west of Fort William, Ont.

Of 51 different machines required by the Cobalt Concentrators for the Nipissing Mill, 50 were supplied by Canadian dealers. The plant when completed will treat 100 tons of ore per day.

Plans are being prepared for the new half-million technical school to be erected on Bloor street, Toronto. It will be complete in every detail and will be planned to allow extensive enlargements.

The new machine shop for the Canadian Rand Company, at Sherbrooke, Que., is completed and the machinery is partly installed. Rock drills, air compressors and mining machinery are being manufactured.

Two 75 kilowatt belted type alternators with two generator panels, two lighting panels and a 25-light series a.c. arc light outfit, all of C. G. E. make, were recently purchased for the Hosimer mines, Hosimer, B.C.

The contract for the new pattern storage vault, 80x50 feet, for the Paris Plow Co., Limited, Paris, Ont., has been awarded to John Carnie, contractor, Paris. It will be of fireproof construction throughout

E. Warren and A. G. Penman, of Toronto, representing the Canadian Smelting & Refining Company, Toronto, were at Sault Ste Marie, Ont., arranging for the construction of a mammoth smelting works at that place.

The Waterman Company has purchased property at St. Lambert, Que., and a large plant for the company's sole Canadian manufacture of pens will be erected. The factory will be of brick and stone, and five storeys high.

The Hinton Electric Company, of Vancouver, B.C., are installing a 500-light electric plant at the Canadian Sulphite Pulp Company's mill at Swanson Bay, B.C. They are using a C.G.E. 25 kw. direct current belted type generator.

The electrical equipment of the C.P.R. shops, Vancouver, has recently been augmented by the purchase from the C. G. E. Company of three 75 kw. transformers, and thirteen induction motors, ranging from 75 h.p. down to 5 h.p.

The Fort William Car Company purposes to build a car works at Fort William. The promoters have guaranteed a plant to employ about 800 hands at the outset, the number to be increased to 1,500 in the course of five years.

To meet with their increased business, the Shawinigan Lake Lumber Company, of Victoria, B.C., have recently installed a new circular saw and edger; these machines being driven by a 30 h.p. 900 r.p.m. Allis-Chalmers-Bullock induction motor.

The Fraser River Sawmills, Millside, B.C., will install a complete new mechanical equipment in the engine-room and to increase the capacity of the plant to a quarter of a million feet of rough lumber per day. The changes to be carried out will aggregate in value $100,000.

A factory for the manufacture of Mitchellite, the new explosive, will be erected near Victoria, B.C. This new invention has given highly satisfactory results during recent trials. Its high explosive power, combined with its safety and absence of poisonous gases, recommends it to builders and contractors.

The Columbia River Lumber Company, of Golden, B.C., have duplicated their present power plant. The new outfit consists of a 75 kw. 3 phase 60 cycle 2,300 volt generator, 4 kw. exciter and two panel switchboard, all of Allis-Chalmers-Bullock manufacture; also a 14-inch by 14-inch Robb-Armstrong horizontal engine.

Messrs. Smith, Kerry & Chace, of Toronto, have been engaged by the city council of Port Arthur, Ont., to make a survey of Silver Falls, Dog Lake, and prepare plans and estimates for a power plant. The ultimate capacity of the works will be 30,000 horse-power, although the present development will probably be confined to about 6,000 h.p.

The C.P.R. Company has erected a cold storage plant at Liverpool, covering an area of 60,000 square feet. The power for working the compressors is obtained from two Crossley gas engines of 45 h.p. each. These engines are supplied with fuel by one of Crossley's patent suction gas plants. Crossley's Canadian agency is Laurie & Lamb, 212 Board of Trade building, Montreal.

The Aetna Machine Co., 214 St. James St., Montreal, have made arrangements with C. Richard & Co., Montreal, for the building of Eclipse hand saws, of which the Aetna Co. hold the patents for Canada. The feature of this machine is the improved treadle, which eliminates dead centres and saves lost motion. It will appeal to all wood-working shops where power is not used.

The British Columbia Electric Railway Company, of Vancouver, recently received a 200-light series alternating current arc lighting outfit for the city of Vancouver. This makes a total of 850 arc lights in that city. The outfit was purchased from the Canadian General Electric Company. They have also ordered, from the same company, twenty-six "C. G. E., 67" four-motor equipments.

On November 15th the railway and manufacturers' committee decided to bring in a by-law at the next meeting of the council of Guelph, Ont., to provide $52,000 for the distribution of Niagara power throughout the city. The net annual gain to the city is figured at $10,000, on

the basis of a 1,500 horse-power contract. Of this amount 750 horse-power will be used by the public utilities of the city.

The Goldie & McCulloch Co. are building, and will soon have installed a 200 h.p. producer gas plant at their north works, Galt. The prospects are that they will largely go into the manufacturing of this system of power production—an important addition to Galt industries. Another Galt firm is also negotiating with the builders for a 175 h.p. gas producer plant, which the builders guarantee will not exceed $5 h.p. per annum.

The National-Acme Manufacturing Co., of Cleveland, Ohio, one of the largest companies in the United States, manufacturing the Acme automatic multiple spindle screw machines, as well as set screws, cap screws, and special milled products, etc., have practically decided to establish a branch of their works in Canada, which will enable them to better supply the growing demand for their product in this country. The location of the plant has not been finally decided on.

A model non-littiug railway spike has recently been patented by John McNeil, of Reserve, C.B. Accordiug to the patentee, the new railholding device will be a boon to the railway companies. The spike is so constructed that after it has been driven into the sleeper a small spring is wedged out under the bottom of the rail, thereby doing away with all possibility of the nail drawing away from its original fasteuing. Most of the big railway wrecks are accounted for ou investigation to have been caused through rail-spreading, owiug to the spikes becoming loose. Mr. McNeil claims that where his iuvention is used, the chance of accideut through such cause would be greatly lesseued. It is understood that Sir Wm. Van Horne is interested in Mr. McNeil's invention, and will give the new spike a tryout on the C.P.R. The article has been patented in Canada and the United States.

Companies Incorporated.

Glenn Stove and Furnace Company, Toronto, capital, $50,000; to manufacture and deal in stoves and plumbers' fittings. Directors, W. G. Glenn, J. McQuaker, E. G. Morris, all of Toronto.

McDougall and Cuzner, Ottawa; capital, $30,000; to conduct a retail hardware business. Provisional directors, W. F. Cuzner, J. P. Brown, W. Robertson and J. Bishop, all of Ottawa.

The Automatic Grain Shocker Machine Company, Hamilton; capital, $100,000; to manufacture farm machinery. Provisional directors, C. T. Grantham, A. E. Osler, A. Zimmerman, all of Hamilton.

B. Bell & Son Company, Toronto; capital, $200,000; to manufacture and deal in machinery, implements and supplies. Provisional directors, S. H. Chapman, H. H. Hurd, C. Morris, all of Toronto.

Toronto Brass Mills, Toronto; capital, $500,000; to manufacture and deal in brass and other castings. Provisional directors, A. E. J. Blackman, A. Munro, J. E. Fennell, A. J. Algate, all of Toronto.

Toronto Iron Works, Toronto; capital, $40,000; to carry on the work and business of a foundry, machine shop and boat-building establishment. Provisional directors, W. A. Manion, H. B. Malone and J. H. Malone, all of Toronto.

Standard Automobile Company, Toronto; capital, $40,000; to deal in automobiles and carry on the business of mechanical engineers. Provisional directors, A. R. Bickerstaff, T. A. Silverthorn, M. G. Carroll, Nora Corcoran, all of Toronto.

Soss Invisible Hinge Company, Toronto; capital, $40,000; to manufacture and deal in hardware specialties and obtain the rights for the Soss invisible hinge. Provisional directors, J. Soss, New York; S. King and F. Watts, both of Toronto.

North Star Oil & Gas Company, Chatham, Ont.; capital, $36,000; to carry on a general mining and development business. Provisional directors, J. H. Teall, E. C. Jackson, and J. W. Cuthbertson, all of Tillsonburg, and F. T. Merrill, Chatham.

Bice Regulator Company, London, Ont.; capital, $70,000; to manufacture and deal in boiler feeds, regulators, valves and all kinds of boiler supplies. Provisional directors, G. Russell, Ethel M. Lindsay, both of Toronto, and A. W. Bice and M. Owen, both of London.

Municipal Undertakings.

A waterworks system will be installed at Port Moody, B.C.

Brandon, Man., is installing a lighting plant for its pumping station.

A waterworks plant will be installed at Elmira, Ont., to cost $25,000.

The council of Kelowna, B.C., has passed a by-law to raise $0,000 for waterworks.

Montreal will try to bring natural gas from St. Maurice county to supply the city with lights.

The road commission of Montreal has asked for the council to vote $40,000 for a sewer on St. Denis street.

Several citizens of Humbolt, Sask., are organizing a company to supply the town with a telephone system.

A by-law was carried in Chesley, Ont., for $38,000 for waterworks. The supply will come from artesian wells.

The Minneapolis Street & Town Lighting Company, Minneapolis, Minn., is seeking a franchise to supply Carnduff, Sask., with electric light.

The shareholders of the Sherbrooke Light, Heat and Power Company, Sherbrooke, Que., are in favor of accepting the city's offer to buy the plant.

Lewis P. Nott, of Montreal, has been awarded the contract for the construction of section 1 of the Trent Valley canal by the Department of Railways and Canals.

The city council, London, has decided to submit a by-law at the January elections, providing for the expenditure of $235,000 for transmission of Niagara power to that city.

The by-law for the new waterworks improvements at Wellaud has been prepared. For this purpose $15,800 will be required. A report has also been received on a new sewerage system.

The Canadian General Electric Co. has been awarded the coutract for $24,672, by the city of Ottawa, for electrical supplies necessary for the taking over of the system of street lighting.

The township of Stamford, near the city of Niagara Falls, have decided to light the highways by electricity, and have entered into a contract with one of the lighteng companies to that eud.

The city council of Quebec, Que., received a communication from the St. Laurent Saw & Steel Works, Sorel, Que., stating that the company would establish a works in that city if certain privileges were granted.

Thamesville is voting this week on a proposition to bonus the Thamesville Box & Handle Co. to the extent of $7,500 with a fixed assessment of $2,000 for 10 years. The factory is to cost not less than $12,000, and to employ 25 hands the year round. Jas. Galloway and D. J. Davies are behind the enterprise.

The city of Victoria has recently purchased through the Vancouver office of Allis-Chalmers-Bullock a complete rock crushing plant, including a No. 5-D Gates breaker, a No. 5 single head 25-foot elevator, a 30 h.p. induction motor, and a complete set of screens. This outfit will be used in the extensive street reconstruction which is about to be begun.

The Department of Marine and Fisheries, Ottawa, will shortly call for tenders for the construction of a large ice-breaking steamer to be used in keeping the channel hetween Prince Edward Island and the mainland open in the winter time. The new steamer will cost about $600,000, and will be one of the largest and most powerful ice breakers in the world.

The Ontario Government has awarded to Purdy, Mansell & Co., Toronto, the contracts for the heating, plumbing, and ventilating of the new Normal Schools at Hamilton, Stratford, Peterboro, and North Bay. The contracts for the electric wiring in the same buildings go to Fred. Armstrong & Company, Toronto. The aggregate amount of all the contracts is in the neighborhood of $63,000.

Railroad Construction.

The C.P.R. is installing its own water-pumping plant at Brandon, Man. The offer of the city was declined.

The C.P.R. will make Grand Forks, B.C., a divisional point, and will spend $100,000 in erecting roundhouses, shops and yards.

Work on the proposed railway from Port Simpson, B.C., to Fort Churchill, on the Hudson, Bay, will be commenced next summer.

Now that the Dominion Copper Co.'s smelter is out of commission for the time being, the B.C. Copper Co. is able to get additional supplies of coke from Coleman, Alberta, much improviug the situation at that smelter.

Boundary Copper Mines, in British Columbia, have shipped more than five and a half million tons of ore, running over a million for this year alone. This is equivalent to more than 100,000,000 pounds of refined copper.

The contract for the construction of the Copper River and Northwestern Railway, in Alaska, has been awarded to M. J. Heney, of Seattle. The cost is estimated at about $25,000,000. E. C. Hawkins, of Victoria, will be chief engineer.

About fifty miles of rails have now been laid on the National Transcontinental on the Quebec section, and grading is well advanced for a long distance on the various divisions now under contract. It is thought that by next fall about four hundred miles of road will be graded, and the track will he laid on a large portion of it. Tenders for the greater portion of the remaining thousand miles between Winnipeg and Moncton will be called for next spring. The contractors on the sections now under construction are reported to be making satisfactory progress.

Everything is now booming at the collieries and at the blast furnaces of the Nova Scotia Steel & Coal Company. During the month of October, 57,071 tons of coal were raised, an increase of 8,415 over September. In the steel department, great activity prevails, and the output of every branch of the plant shows an increase over the previous month. The output of pig iron was 5,755 tons, an increase of 300 tons over September; the steel output reached 6,986 tons, an increase of 1,476 tons over September; while 8,772 tons of coke were produced, being 1,100 tous more than during the previous month. This company will also open up another colliery.

Speaking of the general progress of the construction of the lines of the company in the west, Wm. Whyte, second vice-president of the C.P.R., stated that during the past season there had been but one difficulty and this had been the lack of railway ties. Through traffic to Edmonton would be possible over the new line early next season. The Pheasant Hills brauch, which will run through Edmonton in connection with the Yorkton line, is being operated to Nokomis. The steel has been laid to Lanigan, the point of juuction with the Yorkton branch, and steel has also been laid for a distance of twenty miles beyond Lanigan. Work was heing pushed in the more distant west with the greatest energy and it was hoped that the company would be able to operate the line into Saskatoon by the end of the present month. The grading of the line would also be completed into Lanigan from the east on the extension of the Yorkton line this fall.

Building Notes.

A large rink is being erected at Orillia.

A post office will be erected in Kincardine, to cost $17,000.

E. J. Evans, Toronto, will erect a hotel to cost $18,000.

The valuc of buildings erected in Regina, Sask., during 1907, is $1,103,435.

The new building for the Montreal Sailors' Institute will cost $60,000.

Loo Gee Wing, Vancouver, B.C., will erect a business block to cost $80,000.

A new Oddfellows' temple will be erected at Niagara Falls, Ont., to cost $25,000.

The I.O.O.F. lodge, of Hamilton, will improve their hall at a cost of $10,000.

Charlotte St. Methodist church, Peterboro, will erect an edifice to cost $30,000.

The chartered congregation of the Temple of Solomon, Montreal, to cost $52,000.

The West End Baptist church, Halifax, N.S., was destroyed by fire, the loss being $10,000.

The Canadian Birkbeck Investment and Savings Co., Toronto, will erect an office building to cost $120,000.

Building permits in Victoria, B.C., for October aggregated $81,875. This is an increase of $20,000 over September.

W. J. Cavanagh, Vancouver, B.C., has plans prepared for a large hotel to be erected in that city at a cost of $100,000.

The International Harvester Co., Hamilton, are contemplating the erection of a distributing warehouse at Port Arthur, Ont.

The contract for the new armory for Medicine Hat, Alta., has been awarded to A. Burns, of that city. The cost is $160,000.

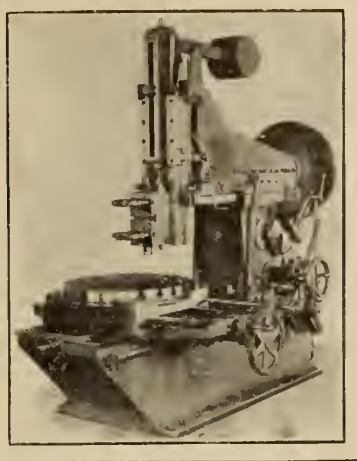
A transportation building will be erected at the Exhibition Grounds, Toronto, to cost $95,000. It will have a floor space of 40,000 square feet.

The contract for a Church of England cathedral in Halifax, N.S., has been awarded to S. M. Brookfield, of that city. The building will cost $125,000.

The directors of the Montreal Dominion Park Company have decided to start at once the rebuilding of that portion of their amusement buildings recently destroyed by fire.

Tenders are invited by the chairman of the Farm Committee, Shawbridge, Que., for an industrial school to be erected on the farm of the Boys' Home, Montreal.

The building total in Winnipeg, Man., for October is $132,450. There were ninety-five permits issued, covering ninety-six buildings. In October, 1906, there were 305 permits issued, covering 355 huildings, at a cost of $1,091,950.



The Dill Slotter

a Great Time and Labor Saver

¶ The Dill Slotter will do more work, and do it quicker and better, than any other Slotter in the world.
¶ No Slotter but the **Dill has the Traveling Head** by which the **tool can be fed to the work**, when (as often happens) the work is too big to be fed to the tool.
¶ The Dill has one third more changes of speed than any other Slotter. And it has a great many other features peculiar to the Dill alone, which place it in a class by itself.

IT WILL PAY YOU TO WRITE FOR THE DILL BOOKLET.

THE DILL SLOTTER PEOPLE

(33rd Ward) PHILADELPHIA, PENNA.

Building permits in Edmonton, Alta., for October, total $78,560, a large falling off from previous months. This has been the case in nearly all the larger cities in the west, as well as in the east, and is an indication of a slight curtailment of buildings, as the results of the financial stringency. This curtailment, however, is far less here than in rival cities of Edmonton.

Trade Notes.

The Evans Rotary Engine Company, Limited, Toronto, is supplying Jonas Byer, Stouffville, with a 75 h.p. rotary engine for his electric lighting plant.

The Chapman Double Ball Bearing Company has secured the contract to equip the works of the Wabasso Cotton Co., Three Rivers, P.Q., with their double ball bearings.

The new terminal station at Hamilton is now occupied by thirteen electrical companies. It was erected by the Dominion Power and Transmission Company, under the supervision of Charles Mills, Hamilton, at a cost of $250,000.

The Colonial Engineering Co., of Montreal, has offered to install producer gas plants in London and Toronto, with a guarantee that the city's light shall not cost over $30 per lamp, including all operating costs, maintenance, interest and depreciation.

The Ferracute Machine Co., of Bridgeton, N. J., manufacturers of presses and dies for sheet metal work, made shipments of their presses last week to India, Austria and England. They intend giving more attention to their Canadian trade and their advertisement appears in this issue.

The Smart-Turner Machine Co., of Hamilton, Ont., report supplying a large number of companies with their feed and vacuum pumps. These include the Brantford Roofing Co., Brantford, Ont.; Steamwinder Gold & Coal Mining Co., Fairview, B.C.; Beamsville Preserving Co., Beamsville; Canadian Asbestos Co., Montreal; Sherlock Manning Organ Co., London, Ont.; Somerville Ltd., Toronto; Victoria Industrial School, Mimico; Helena Costume Co., London, Ont.; two to the G.T.R. and six to the I.C.R., Moncton.

Expanding Their Business.

In this issue is the announcement of the H. W. Petrie, Limited. This expansion is due to the increase in trade, and in order to extend their rapidly growing business more capital has been interested, and the company is in a better position than ever to look after the needs of its customers.

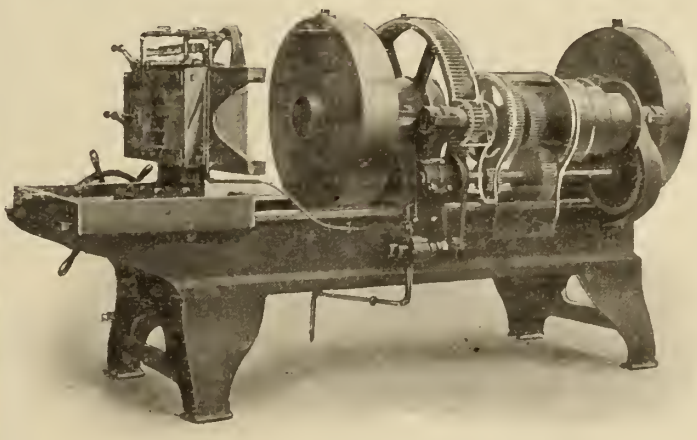
New Factory for Stratford.

A Canadian branch of the Allen P. Boyer Company, of Goshen, is being opened in Stratford, Ontario. A two-storey brick building, 100 by 68 feet, is being erected on a ten-lot site on King street, and the company will employ 25 to 40 hands at the outset. They will manufacture various kinds of swings, ladders, hay slings, carriers and forks. It is intended to put $40,000 into the company here.

Tremendous Power to be Harnessed.

A company has been formed in Vancouver, the British Columbia Power and Electric Company, who have obtained a site on the Chekamus river, forty-eight miles from Vancouver, where the river has a drop of 520 feet in 600

PIPE CUTTING and THREADING MACHINE



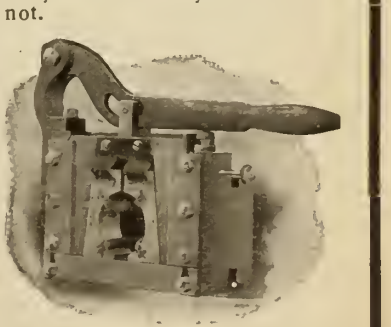
—*INTELLIGENT IN DESIGN*
—*MODERN IN CONSTRUCTION*
—*SIMPLE IN OPERATION*
—*PERFECT IN RESULTS*

SHANTZ NO. 6

¶ This machine cuts absolutely perfect threads on 1½-inch to 6-inch pipe. It does the work with one cut, and does it quicker and cleaner than any other machine in America. Weighs 4,300 pounds, and is so immovably rigid that a wavy thread is an impossibility.

¶ It is fitted with the "**Borden Patent Solid Adjustable Die Head**" which is the easiest operated and most perfect mechanism on any Pipe Threading Machine. Any degree of accuracy may be obtained simply by the adjustment of an adjusting screw upon which the operating lever rests. Any variation may be obtained. to suit any make of fitting, whether standard or not.

¶ How long have you been "getting along" with the old machine, losing time and money and your patience every time you have any pipe-threading to do? No necessity to do this any longer. Our machine is a time and money saver and we can prove this to your satisfaction. It will stand up to its work—no matter how hard you work it or how hard the work is. We will be glad to tell you about the many special features.



Write *TO-DAY* for Circular fully describing this machine

I. E. SHANTZ & CO., BERLIN, Ont.

feet. It is estimated that there is 250,000 horse-power, and it is proposed to make provision for a plant that will supply 100,000 horse-power in Vancouver.

Car Shop for Hamilton.

The Dominion Power and Transmission Company, of Hamilton, will begin work in the spring on an immense new freight shed, car shops and sheds for the cars used by the various electrical companies using the new terminal station. The scheme includes a car manufacturing industry, which will turn out the cars required for the different lines. The site will be on Sanford avenue, and plans are now being prepared.

New Factory at Galt Starts Work.

The Car & Coach Company, of Galt, have started business and are in need of more men. The engine room, smoke stack and coal pit are completed and are permanent. As soon as weather conditions will permit in the spring a main work shop, car-erecting shop, transfer table, an office and two additional buildings will be erected. At present a temporary main building, 160x76 feet, will be used to carry out the orders now in the hands of the company. This will be replaced in the spring by a reinforced concrete structure, 120x65 feet, and three storeys high.

New Plant for Montreal.

The Metal Shingle & Siding Co., Montreal, manufacturers of herringbone lath and truss beam fabric for concrete reinforcement have installed in their new plant some up-to-date machinery. They intend manufacturing, in addition to their special line dies, tools and gauges. Among other machinery they have installed a Brown & Sharpe No. 3 surface grinder with magnetic chuck, and a No. 3 Universal grinder and milling machine, fitted with differential driving head. They have also a modern hardening and tempering plant for either carbon or high speed steels.

Hamilton Steel & Iron Co.'s Plant in Full Swing.

With the starting of the new furnace at Hamilton the capacity of this company has been doubled. The new furnace was installed at a cost of over half a million dollars, and has a capacity of 300 tons of foundry iron, or 400 tons of basic iron, used in the manufacture of steel. The location of this second furnace in Hamilton means a large addition to the number of men employed. The furnace is equipped with many labor saving devices for handling ore and pig iron and the company will be able to turn out much more steel than in the past and will thus be in a better position to supply the demand.

Electric Power Plant at Middle Falls.

On Oct. 25th the ratepayers of Campbellford, by a vote of 296 to 6, carried a by-law to build a $60,000 power plant at Middle Falls. The contract for the dam has been let to Brown & Alymer, and Bogue & Buchanan, of Peterboro, will erect the power house.

The power house is being erected as a municipal enterprise to supply power users in the town, and also to generate electricity for street lighting. The plant will be a modern one in every respect, and will be placed in operation at as early a date as possible.

Electrical Development at Healey Falls.

Construction operations on the Northumberland-Durham Power Co. at Healey Falls and rapids is advancing under the supervision of Managing Director Culverwell. The company is now constructing two different power developments, one being a dam at the foot of the lower rapids to flood the water back on the top and several chains above the big falls, this being done to hold the Ontario Government lease. This will be completed if the Dominion Government do not settle with the company as to their portion of the upper rapids which intervenes the Ontario Government lease portion and portions of the upper rapids owned by the company.

The other where work is going on also, which the company hopes they will be allowed to finish, is a four thousand-foot head-race to extend from above the bridge along the high table and on the southwest side, to a point nearly opposite the foot of the rapids, and from that point the water will be carried down the hill to the power house by two twelve-foot pipe lines. This head-race would give a total head or fall of seventy-three feet.

This power, with reservoir above, would give fourteen thousand horse-power during working hours of day in dry season, which the company wish to supply to the whole of south midland Ontario.

New York capitalists visited Healey Falls recently, with Managing Director Culverwell, and their engineer drove over the projected electric railway to connect the C.P.R. at Havelock with Campbellford, Warkworth and Cobourg, and Port Hope, with branches—one of which will connect Hastings with Brighton, making a junction at Warkworth. Mr. Culverwell and his associates will apply for this charter at the session of the local Legislature.

Brass Mills to Re-open.

President Menzies, of the newly-formed Toronto Brass Rolling Mills, with mills at New Toronto, states that the mills will be re-opened as soon as arrangements are made for a new manager for the works. The plant has been closed down for a couple of years, the old company, the Canada Brass Rolling Mills, having been wound up by foreclosure in August. The new tariff is favorable to the operation of the mills, the duty on brass sheets, rods and tubing having been increased in November, 1906, since which time users of brass have been forced to import and pay the duty, no supply being available from a Canadian mill.

Proposal to Enlarge Doty Engine Works.

The Doty Engine Works Company, of Goderich, Ont., has made a proposal to the council of that city that in return for $35,000, repayable in yearly instalments, with interest at 5 per cent. per annum, also exemption from taxes for a term of ten years, including school taxes, they will erect extensions to their plant and employ 100 hands continually. The new plant will be devoted to the manufacture of boilers and steel furnaces for steamers, and structural materials, and will be located on a site convenient to the railways. The company will accept the town debentures and finance them.

New Machine Shop.

The American Auto-Engine Co. are a new firm who have recently opened up a machine shop in Montreal. They have erected a one-storey building at the corner of St. Louis and Bonsecours streets. This is 42x60 feet, and will all be used as a work shop, with the exception of a space 18x20 feet, which has been separated off to make two rooms, an office and pattern room. This firm have also procured a building at the rear, which they will convert into an automobile garage. Considerable up-to-date machinery has already been installed and more will be put in later on. They are manufacturing marine and stationary gas and gasoline engines, and are also making a specialty of fine repair work. At present the power used is steam, but they have under construction a large type of engine of their own particular make.

Berlin Machine Works, Limited, Hamilton.

This company has almost completed its new plant in Hamilton and by January 1st will give employment to 150 men. The company will manufacture a complete line of wood-working machinery, including planers, surfacers, matchers, sanders, saws, band-saws and molders.

The company purchased twenty acres of land at the intersection of the G.T.R. main line to Buffalo and the T. H. & B. railway. The plant, including machine shop, foundry and power house, was erected under the supervision of Mr. G. W. Robinson, secretary and resident manager. Motor drive will be employed, lighting will be by Cooper-Hewitt and Nernst lamps, while for babbiting and tempering furnaces, natural gas will be used.

The power house, 90x50 feet, is of brick and steel construction, and contains heating plant, Westinghouse motor generators, Cataract power transformers and Curtis air compressor. A chimney 110 feet high, is being erected by the Weber Steel Concrete Chimney Co.

The foundry, 200x72 feet, has a capacity of 30 tons per day. A reinforced concrete gallery, back of the cupolas, affords storing space for sand and coke. The foundry equipment consists of Whiting and Newton cupolas and Root blowers,, the Sly system of tumbling barrels and dust collector and a Powling & Harnischfeger 15-ton electric traveling crane. There are also twenty indepentent jib cranes for use of the molders.

The machine shop is also of brick and steel, 300x200 feet. The machinery will be driven by what is known as group drive. A gallery, 200 x48 feet, will be used for a tool room. The machine shop will be equipped with over seventy machine tools run by Westinghouse motors from 5 to 75 h.p. capacity. Two Pawling & Harnischfeger 10-ton electric traveling cranes have been installed. These buildings will accommodate over 700 men. Plans have been prepared for a number of other buildings, which will be erected in the spring. These include a pattern shop, pattern storage vault and a chemical laboratory.

More Power for Montreal.

The big project of the Montreal and Provincial Light, Heat and Power Companies, at the Coteau de Lac rapids, thirty miles from Montreal, is nearing completion and power will be used from this source in Montreal this autumn. A million and a half dollars have been spent on this plant, which is expected to develop 15,000 horse-power. The plant is complete in every detail and includes a canal, half a mile long, an immense reinforced concrete dam, penstocks and draft tubes, as well as a large power and wheel house.

Canada's Peat Beds.

James Murray, of Woodstock, has discovered a valuable peat bog on his farm, at West Zorra, and will immediately take steps towards its development. An expert has been consulted and on examination the bog was found to be an inexhaustable bed of peat. A plant will be put in operation and peat briquettes manufactured for general use.

It has been estimated that Canada has 37,000 square miles of peat lands. At one time a Government commission was appointed to examine and report on the principal peat industries in Europe, with a view to turning the extensive peat bogs to good account. So far the reports have not been made public and this resource has not been utilized. The wide-spread coal fields of America have been supplying us with fuel, and this can be had with less work than digging, drying and pressing the peat. Until the coal supply runs short we can hope for little advance unless some cheaper method is devised for curing the peat. In Europe peat is converted into paper and wood alcohol is extracted from it, so that progress is being made along this line. A company, manufacturing peat at Orlando, Florida, lets the peat dry by natural processes, and then breaks it into lumps for sale. Should the Canadian peat-beds be developed and the output sold at a moderate cost, it will, no doubt, find a ready market.

C.P.R. Land Holdings.

The Canadian Pacific Railway occupies a unique position in the railroad world, in the possession of valuable assets, altogether distinct from the properties and equipment necessary for the conduct of its business. At the close of the last fiscal year there remained unsold out of the original grant of lands by the Government, 8,905,823 acres of agricultural land, besides 3,419,673 acres in British Columbia, and 2,500,000 acres, also in British Columbia, which the company is to receive through the Columbia & Western Railway. The Canadian Pacific, then, after all its profit-taking from land sales extending over 20 years, still has possession of the enormous amount of 14,825,496 acres of land, free from bonded debt, which is rapidly appreciating in value.

MANUFACTURERS AND MANUFACTURERS' AGENTS.

It will pay you to watch our condensed column each month. There are many money-making propositions brought to your attention here. You may find just what you are looking for.

RATES

One insertion—25c. for 20 words; 1c. a word for each additional word.

Yearly rate - $2.50 for twenty words or less, 10c a word for each additional word.

The above does not apply to notices under the head of "Machinery Wanted." These notices are inserted free for subscribers.

FOR SALE.

BELTING, RUBBER, CANVAS AND LEATHER, Hose Packing, Blacksmith's and Mill Supplies at lowest price. N. Smith, 138 York Street, Toronto. (2tf)

MARINE gasoline engine castings, with blue print and full instructions, etc.; 2½, 4, 6 h.p.; also complete finished outfits at $65 up; catalogue, Krug & Crosby, Hamilton. [10tf]

FOR SALE—Complete outfit of modern hardwood flooring machinery; Beliot and Hoyt matchers, Fay-Egan double planer, Cowan broken roll surfacer, Sherman end matcher and boring machines; also dry kiln outfit, with steel cars; latest style of tools and practically new; no scrap iron. J. S. Finlay, Owen Sound.

FOR SALE—All machinery, tools, motors and equipment contained in machine shop, pattern shop, molding shop and boiler shop of William Hamilton Company, Limited, manufacturers of saw mill machinery, water wheels, mining machinery and contractors' supplies, Peterborough; will be sold in parcels or en bloc. Apply to R. R. Hall, Peterborough, Ont.

HOISTING ENGINES—We have for immediate shipment three 6½ x 8 and three 7 x 10 double cylinder, double drum steam hoists; also six single drum horse power hoisting machines. The Manson Mfg. Co., Limited, Thorold, Ont.

FOR SALE—The Canadian patent rights on a valveless pneumatic hammer, proved by actual test to be experience to any hammer at present on the market; an arrangement can be made to manufacture same on royalty for Canadian market. Apply Box 39C, CANADIAN MACHINERY, Toronto. (12)

SITUATIONS WANTED.

MOLDER—Machinery, first-class man, 15 years' experience in best shops in Detroit and Chicago. R. A. Nash, Sarnia, Ont.

WANTED—Position as purchasing agent or correspondent for manufacturing firm by a young man at present employed in a similar capacity by one of the largest manufacturing concerns in Ontario; has had long experience in these lines, thoroughly understands all branches of office work and can furnish best of references. Address Box 43, CANADIAN MACHINERY, Toronto. [12]

MECHANICAL engineer (25) seeks position; experienced in construction of modern copper, zinc, smelting works, machinery furnaces, etc.; general engineering, gas, steam engines, suction and pressure gas plants; structural steel, etc.; reliable, energetic; good references. Box 27, CANADIAN MACHINERY, 88 Fleet St., London, Eng. [12]

LARGER PREMISES WANTED.

THE VALLEY CITY SEATING CO., LIMITED, is desirous of enlarging their premises, or would consider proposition to purchase furniture or woodworking plant if modern and located in good town. Address all communications to J. D. Pennington, Dundas, Ont.

AGENTS WANTED.

A Firm of Chemical Engineers

are requiring first-class agents in the large cities of Canada. Apply to W. J. Fraser & Co., Ltd., Chemical Engineers, 98 Commercial Road East, London, England. [11]

FOR SALE

15 Ton Traveling Crane

hand operated.

46 ft. rail span.

47 ft. 1½ in. extreme length.

4 ft. 10⅝ in. from runway rail to highest point of crab.

About 25 ft. lift.

Crab runs on top of two parabolic bridge girders.

Made by Whiting Foundry Equipment Co., 1903.

Of good construction and in excellent order. Has been used only for erection of machinery in an electric station, i.e., has been actually working but a small fraction of the period of its installation and has not been subjected to dust or weather.

Reason for disposal is the need of a larger crane.

Communicate with

THE SHAWINIGAN WATER AND POWER COMPANY

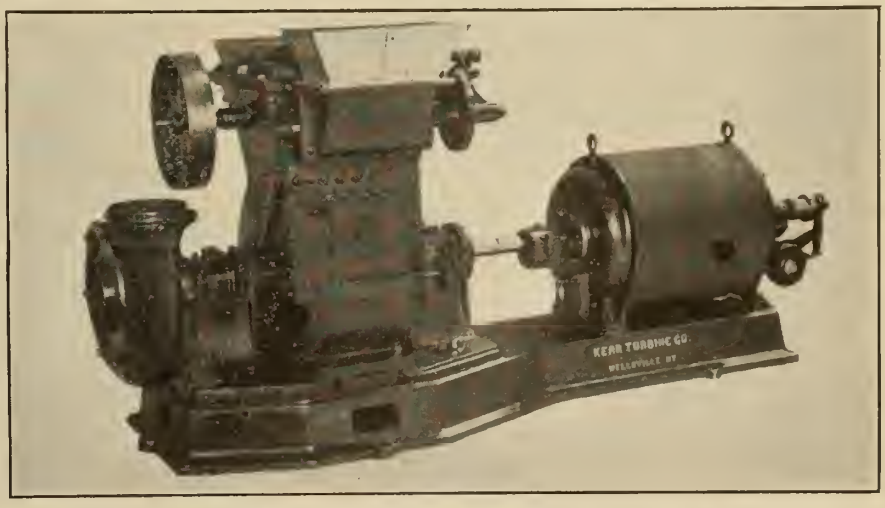
MONTREAL, P.Q.

Persons addressing advertisers will kindly mention having seen advertisement in this paper.

ANNIVERSARY NUMBER.

Thirty years have elapsed since the inception of the American Machinist in 1877 and the occasion is celebrated by issuing a 532 page anniversary number. This number is their special quintennial edition and is marked by a survey of the progress of machinery development during the past five years and the amount of advertising carried in this number of the journal, 433 pages being occupied by machine tool advertisers.

To the publisher, Mr. Hill, and his splendid organization, Canadian Machinery extends its hearty congratulations and hopes that the prosperity which attends them, and which they richly deserve, may long continue. It is an issue that is worth having because it contains so much real good matter of interest to every manufacturer. Unfortunately, the asinine policy of some of our Post Office officials shuts out a lot of this class of most valuable matter—information that means dollars and cents to Canadian manufacturers and to Canadian people.



12" KERR STEAM TURBINE 25 b.h.b., at 3000 to 3200 r.p.m., coupled to No. 00 RAYMOND PULVERIZER AND AIR SEPARATOR for handling lime, cement, mica, rags, scraps, corn, cottonseed hulls, dry colors and the like.

KERR TURBINE BLOWERS, for gas works, foundries and forge shops. Air pressure 4 to 16 ounces. For any capacity.

TURBINE PUMPS, for water works, condenser equipment and boiler feeding. These pumps are more economical than direct acting piston pumps and require less attention, lubrication and space. No belts or gears. Speed adjustable to pressure desired. Regulation close. Start and stop quickly. For any capacity.

TURBINE GENERATORS, 2 kw. to 150 kw. direct current and alternating current 25 k.w. to 150 kw. 60 cycle.

Built in Canada by WM. STEPHENSON, 34 Bay St. N., Hamilton, Ont.
Main Office: KERR TURBINE CO., Wellsville, N.Y.

Montreal Toronto Winnipeg

THE CANADIAN TURBINE WATER WHEEL

We have not expanded the discharge of our turbines, as we find the results given by our combined impact and reaction runner to be vastly superior to those obtained from turbines of the expanded discharge type. Do not sacrifice your water power. We can save you 20 to 30 per cent. of your water and at the same time give you a much more satisfactory drive.

CHAS. BARBER & SONS, Meaford, Ont.

Turbine Water Wheels, Governors and Gearing only

A Labor Saving Combination

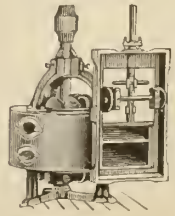
Couch and forming rolls with special attachments for economical manufacture of pipes, complete machines made to meet your requirements (patent 94746), estimates furnished upon application.

Stuart B. Playfair

Traders Bank Building

TORONTO, - CANADA

Improved "LITTLE GIANT" TURBINE WATER WHEEL



Complete in self-contained case. No expensive flume required. 18 sizes carried in stock, prompt shipment insured. Highest efficiency at full or partial gate opening.

Construction, acme of simplicity.

Unequalled durability.

Write for descriptive catalog.

What do you require in

Plumbago Facings?

We can not only fill your wants but do so to your entire satisfaction.

Our range includes 50 grades from 1c. to 10c. per pound.

A pleasure to give you further information.

J. W. PAXSON CO.

PHILA., Pa., U.S.A.

MANUFACTURERS

FOUNDRY FACINGS SUPPLIES

Mr. Manufacturer

Perhaps you have some second-hand machinery around your establishment that is not earning anything for you. **Why not get your money out of it?** Offer it for sale in the Condensed Advt. columns of **Canadian Machinery.** It will only cost you a few cents and you will not be groping in the dark, for every reader is a possible buyer or can influence buying. (See page 65 this issue.)

PROMPT SHIPMENT

Plumbago, Foundry Facings and Supplies

THE DOMINION FOUNDRY SUPPLY CO. *LIMITED*

TORONTO ONT. MONTREAL QUE.

WHAT we PROMISE

To Do in Your Foundry:—

To prevent sticking of molds.
To prevent breaking of molds.
To make a clean quick lift.
To bring out every line of the pattern as clean cut and clear as the pattern itself.

TO SAVE YOU MONEY.

How We Do It.

By selling you **"PARTAMOL,"** the **"NEVER STICK PARTING"**—the only absolutely STANDARD PARTING on the market.

We guarantee it—our users guarantee it.

Sample on request.

Partine

THE UNIVERSAL PARTING.

Trade Mark Reg. U. S. Patent Off.

Preferred by Leading Foundrymen to Lycopodium

Partine does not run, cut, wash or burn off the face of the mould.

Guaranteed to produce, in every instance, a PATTERN TRUE casting, displaying the most delicate lines and features of an artistic design, accompanied by an absolute smoothness of the edges of the metal.

Its price is so low as to make its use imperative in every modern foundry.

Write for free sample, descriptive booklet and full particulars.

DOGGETT'S PERFECTION PARTING

GUARANTEED TO PERFECTLY PART UNDER ANY AND ALL CONDITIONS

For Straight and Difficult Lifts Sticky Patterns Slanting Copes and Deep Chasings

Permits Swabbing and Slicking.

Will not Burn off the Face of the Mould, Wash or Cut.

SUITABLE FOR BRASS, BRONZE, IRON, ALUMINUM

Manufactured by

STANLEY DOGGETT

101 Beekman Street, . New York City, U. S. A.

DISTRIBUTING AGENTS

DETROIT FOUNDRY SUPPLY CO., Windsor, Ont., and Detroit, Mich.

ALSO MANUFACTURE

CHARCOAL and CHARCOAL FACINGS AND ALL GRADES OF SOAPSTONE FACINGS

Woodison Prepared Clay

Next to graphite, the most fire-resisting element known.

For daubing your cupola, ladles, or for setting fire-brick, is unexcelled. Will give better results than three times as much fire-clay.

The price is right, and a barrel can be had for trial. If satisfactory, pay for it; if not, keep it with our compliments.

With us taking all the chances, you should not hesitate sending the order to-day.

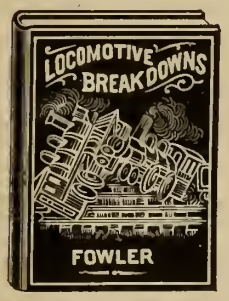
PRACTICAL LITERATURE

For Electricians, Scientists and Engineers

All orders payable in advance.

Locomotive Breakdowns



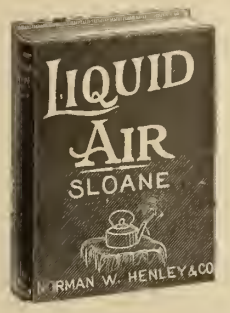
Emergencies and their Remedies

by Geo. L. Fowler, M.E.

Price $1.50, Postpaid.
250 Pages, 96 Illustrations.

This book is an up-to-date catechism treating on all classes of accidents which may happen to locomotive engines and giving the remedy to be applied. [Accidents to the Valves, Cylinders, Valve Motion, Running Gear, Compound Locomotives, Boiler Troubles are treated separately and fully. It tells what should be done in any emergency.

Liquid Air



and the

Liquefaction of Gases

by T. O'Conor Sloane, A.M., E.M., Ph.D.

Price $2.00, Postpaid.
365 Pages, Fully Illustrated.

This book contains the full theory, history, biography and bibliography of the subject from the earliest times, as well as a description of all the wonderful experiments performed with it, showing how liquid air is carried hundreds of miles and handled in open buckets. It also tells what may be expected from it in the near future. Although a work of scientific interest and authority, it is intended for the general reader.

Engine Runner's

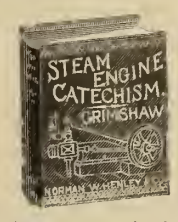
Catechism

by Robert Grimshaw, M.E.

Price $2.50, Postpaid.
354 pages, Profusely Illustrated.

This work gives complete descriptions of the general characteristics of various well-known makes of engines, followed by details of shipping, making foundations, erecting and starting, and the specific instructions as to the adjustment of special makes. Every engineer will find in this volume more really practical and useful information than is to be found anywhere else within a like compass.

Steam Engine



Catechism

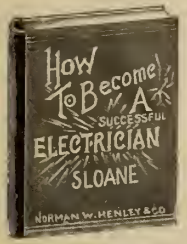
by Robert Grimshaw, M.E.

Price $2.00, Postpaid.
413 Pages, Fully Illustrated.

This book is a series of nearly 1000 direct, practical questions and answers; in fact it contains every essential question on the Steam Engine with its answer. Leading engineers have recommended it as a valuable educator for the beginner as well as a reference book for the engineer. It is intended for

EVERYONE INTERESTED IN STEAM.

How to Become a Successful Electrician



by Prof. T. O'Conor Sloane, A.M., E.M., Ph. D.

Price $1.00, Postpaid
200 Pages, Bound in Cloth.

Every young man whose ambition it is to become a successful electrican should read this book. It is the clearest and most practical book on the subject ever published. Its 19 Chapters include Mathematics, Physics, Chemistry, Electricity at Home, Drawing, Electrical Factory Work, Mechanical and Steam Engineering, the Manufacturing and Constructing Engineer, Inventing, Original Investigation, etc.

Gas, Gasoline and Oil Engines

by G. D. Hiscox, M.E.,

Price $2.50, Postpaid.
450 Pages, 351 Illustrations.

This book is a thorough treatise on the construction, installation, operation and maintenance of gas, gasoline, kerosene and crude petroleum engines. It is the new rewritten enlarged and revised 15th edition of this work giving general information for everyone interested in the popular motive power, and its adaptation to the increasing demand for a cheap and easily managed motor requiring no licensed engineer.

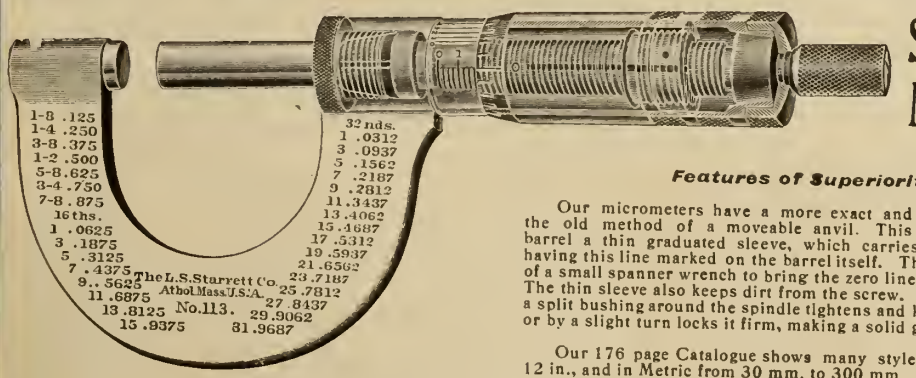
STARRETT TOOLS

ARE THE STANDARD

FOR ACCURACY, WORKMANSHIP, DESIGN AND FINISH



Starrett Micrometers

Features of Superiority—Patented

Our micrometers have a more exact and easier way of adjustment than by the old method of a moveable anvil. This is obtained by placing over the barrel a thin graduated sleeve, which carries the base or zero line, instead of having this line marked on the barrel itself. This sleeve may be turned by means of a small spanner wrench to bring the zero line correct to compensate for wear. The thin sleeve also keeps dirt from the screw. A knurled locking nut contracting a split bushing around the spindle tightens and keeps the spindle central and true, or by a slight turn locks it firm, making a solid gauge when desired.

Our 176 page Catalogue shows many styles of Micrometers, from ½ in. to 12 in., and in Metric from 30 mm. to 300 mm.

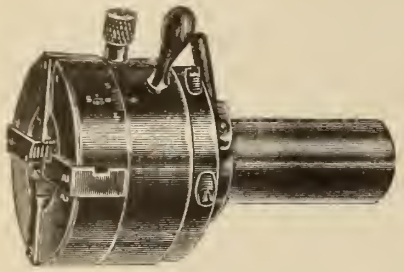
Send for Free Catalogue, No. 173, of Fine Mechanical Tools

THE L. S. STARRETT CO., ATHOL, MASS., U. S. A.

Style "D" Self-Opening Screw Cutting Die Heads

This style of Die Head is arranged for use on the turrets of hand and automatic screw machines —cuts threads of any diameter, pitch, form and length, on steel, iron, brass or other metal.

As its name implies, it is self-opening; the dies opening automatically at the end of the cut, clearing the thread and saving the time required in backing off solid dies, which leaves a good, smooth thread and does away with the stripping and tearing, which is so common in the use of solid dies.



With the aid of extra sets of dies these die heads will cover a very wide range of diameters, an extra set being required for each different diameter cut.

Upon receipt of samples or blue prints, we are always glad to submit quotation and time of delivery on a suitable equipment of tools to cover the requirements.

Shall we send you a copy of our new complete catalogue?

106 N. FRANCISCO AVE., CHICAGO, U.S.A.

Knowledge Is Power

THE SUCCESSFUL BUSINESS MAN is the man who takes an interest in life outside his own business. He is the man who is capable of applying general knowledge, whether gained from reading or otherwise, to his business. It is his capacity to apply this general knowledge to his business that puts him in the **REALLY SUCCESSFUL CLASS.**

How is the average business man to acquire a general knowledge of affairs. He has not the time necessary to search all the various magazines and periodicals for what interests him. Must he trust to one or two publications and miss the many which do not come his way?

NO. There is a method by which he can procure the interesting, timely and instructive articles appearing in every publication, both on this side of the Atlantic and the other.

The Editorial Department of

THE BUSY MAN'S MAGAZINE

carefully ransacks these hundreds of publications, and culls the **choicest** and the **best** appearing in each of them. The readers of the Busy Man's get the Cream of Hundreds for the price of one. Every article is **select.** No turning over a dozen pages to get one good one; every page is interesting. All articles not reproduced are classified under suitable headings, so that any reader can see at a glance what the magazines of the month contain in his line.

A review of the latest books is given in each issue.

This many-in-one magazine will cost you only $2 per year, if you are a subscriber to Canadian Machinery, $1.50. You cannot afford to do without it.

The following opinions of its regular readers prove its value:

"I consider The Busy Man's Magazine the best I have yet come in contact with." Henry Wilson, Toronto.

"It is the most interesting publication of its kind I have ever subscribed to." G. F. Haworth, Toronto.

"There is no better printed in the world to-day for busy men." B. T. Petch, Regina, Sask.

"Your magazine is the best I have ever had the privilege of perusing." S. W. Wynn, Yorkton.

"We would not like to miss the future copies of The Busy Man's Magazine." Ingersoll Packing Co., Ingersoll.

"I am pleased to say that each number is becoming more valuable and interesting." A. B. Musselman, Berlin.

"I am more than pleased with my investment in The Busy Man's Magazine, believing it to be the best magazine I have had the pleasure of perusing." A. B. Burrell, Amigari.

"I have been delighted with the Busy Man's Magazine. The articles are well chosen, are concise and ably written. For a busy man I know of no other magazine that will compare with it." Geo. Anderson, Toronto.

"The articles in The Busy Man's Magazine are just what we want, short and so well written that a busy man can afford time to read them and feel benefitted for the short time given to each article." Wm. Thoburn, Almonte.

Have your subscription commence with our Christmas number, which will be off the press in a few days.

Write us to-day.

THE BUSY MAN'S MAGAZINE

TORONTO

DO YOU KNOW that there is no other magazine in the world that covers the fields of engineering and technology to the same extent or in such a useful literary way as TECHNICAL LITERATURE, and that no other appeals equally to specialists and the general reader in so many branches of the profession? It has become a most valuable companion to such professional men as

Architects	Engineering Students	Hydraulic Engineers	Mechanics	Patent Attorneys
Chemists	Factory Managers	Iron and Steel Makers	Metallurgists	Power Consumers
Civil Engineers	Foundrymen	Irrigation Engineers	Mining Engineers	Railroad Engineers
Contractors	Gas Engineers	Machine Tool Makers	Municipal Engineers	Sanitary Engineers
Draftsmen	Heating, Lighting and Ventilating Engineers	Marine Engineers	Oil, Paint and Varnish Makers	Steam Engineers
Electrical Engineers		Mechanical Engineers		Water Works Engineers

AND OTHERS INTERESTED IN TECHNICAL WORK OR STUDY

Such men may be considered as forming the backbone of the citizenship of the country. They are the men who do things, and who control the expenditure of millions of dollars, involving the purchase of all kinds of material and machinery. If you have anything to offer them for business or pleasure, advertise it in TECHNICAL LITERATURE. *Let us show you the scope, vitality and the power of our circulation.*

ONE ADVERTISER WRITES: "Your magazine is a good one and sure of success. It is going to be looked over by a good class of readers, and our advertisement will not be lost in a mass of ill-digested matter."

ADVERTISING RATES SENT ON APPLICATION

Subscription price, $2.00 a year to United States or Mexico; $2.25 to Canada; foreign countries, $2.50. Single copies, 20 cents.
